## Table of Contents

<b>Program.....</b>	<b>iii</b>
<b>A Framework to Support Coalition Formation in Supply Chain Collaboration.....</b>	<b>1</b>
<b>A Study of Benefits of Information Sharing between Production Systems and Service Centers ..</b>	<b>7</b>
<b>A Study of Corporate Managerial Module and Information System Orienting Agile Virtual Enterprises.....</b>	<b>14</b>
<b>A Study of Single-vendor and Multiple-retailers Pricing-Ordering Strategy under Group-Buying Online Auction .....</b>	<b>19</b>
<b>An E-Logistics Model for Effective Collaborative Commerce .....</b>	<b>24</b>
<b>An XCS-Based Intelligent Searching Model for Cross-Organization Identity Management in Web Service .....</b>	<b>28</b>
<b>Assessment of Service Quality of Logistics Center in Chain Stores Based on Fuzzy Logic and TOPSIS .....</b>	<b>34</b>
<b>Asymmetric Demand Information and Channel Profits When Retailers Compete .....</b>	<b>38</b>
<b>Bidding Strategies Analysis for Procurement Combinatorial Auctions .....</b>	<b>41</b>
<b>Business Interactions with Web Services .....</b>	<b>46</b>
<b>Collaboration Strategy of Business-to-Business Enhancing Customer Satisfaction.....</b>	<b>52</b>
<b>Collaborative Planning, Forecasting and Replenishment: Demand Planning in Supply Chain Management .....</b>	<b>58</b>
<b>Cooperation in Reverse Logistics .....</b>	<b>63</b>
<b>Coordination Mechanisms in the Supply Chain Based E-business.....</b>	<b>68</b>
<b>Decision Model for COTS Component Procurement Based on Case-based Retrieval and Goal Programming.....</b>	<b>73</b>
<b>Design of an E-SCM system for Auto-Parts Companies .....</b>	<b>77</b>
<b>Development Stages of Supply Chain Management in E-Business Environment .....</b>	<b>82</b>
<b>E-Booking Control Problem in Sea Cargo Logistics .....</b>	<b>87</b>
<b>E-Logistics Comparative Positioning Model: A Multi-National Enterprise Airline Study .....</b>	<b>93</b>
<b>E-supply Chain's Implementation in a Transit Economy.....</b>	<b>101</b>
<b>Experimental Study on Effect of Information Behavior by Media Representation Patterns of E-Commerce System .....</b>	<b>110</b>
<b>Generic Supply Chain Management System .....</b>	<b>114</b>
<b>Hierarchical Structuring of a Workflow Model in Petri-Net.....</b>	<b>117</b>
<b>Manufacturing Enterprises Value Chain Model Analysis within the Context of the Network Economy .....</b>	<b>122</b>
<b>On Inventory Strategies of Online Retailers.....</b>	<b>127</b>
<b>On-Demand Business Process Integration Based on Intelligent Web Services .....</b>	<b>132</b>
<b>A Two Phase Verification Algorithm for Cyclic Workflow Graphs .....</b>	<b>137</b>
<b>Pricing Policy for Supply Chain in the Electronic Commerce Environment .....</b>	<b>144</b>
<b>Recomposing of Industrial Supply Chain and Constructing of Digital CBD .....</b>	<b>149</b>
<b>Research on the Supply Chain Partnership Relations with Association Rule Analysis .....</b>	<b>154</b>

<b>Studies on Horizontal Competition among Homogenous Retailers Based on Agent-based Approach .....</b>	<b>158</b>
<b>Study of Information Supply Chain and Artificial Neural Network's Related Application .....</b>	<b>164</b>
<b>Study on Distribution Patterns of E-Business Based Agricultural Products Logistics .....</b>	<b>169</b>
<b>Study on Supply Chain Management in Electronic Commerce.....</b>	<b>175</b>
<b>Supply and Demand Management under Inducement of Price Discounts – A Monte Carlo Simulation Analysis .....</b>	<b>180</b>
<b>Taking Advantage of E-Logistics to Strengthen the Competitive Advantage of Enterprises in China.....</b>	<b>185</b>
<b>The Distribution Network Planning Using Geographic Information System (GIS).....</b>	<b>190</b>
<b>The Impact of IT Capability and E-Business on the Supply Chain Performance.....</b>	<b>193</b>
<b>The Implementation of an Intelligent Logistics Tracking System Utilizing RFID .....</b>	<b>199</b>
<b>The Operating Cost in a Tele-working Organization.....</b>	<b>205</b>
<b>The Virtual Service Value-Chain: Disruptive Technology Delivering Competitive Advantage for the Services Industry .....</b>	<b>211</b>
<b>The Web Services on Mobile Shopping Automation.....</b>	<b>219</b>
<b>Trust, Relationship Commitment and Supply Chain Integrations in China .....</b>	<b>223</b>
<b>A Comparison of Brand Loyalty in Online and Physical Channels: An Empirical Application to Supermarkets .....</b>	<b>229</b>
<b>A Defection Detection Procedure Using SOM and Markov Chain : A Case of On-Line Game Provider .....</b>	<b>233</b>
<b>A Global Comparative Study of Online Auction Markets .....</b>	<b>239</b>
<b>A Model of Customer Lifetime Value Consider with Word-of-mouth Marketing Value .....</b>	<b>245</b>
<b>An Exploratory Study of the Effects of CRM Practices on CRM Effectiveness and Business Performance .....</b>	<b>249</b>
<b>An Intelligent Model for Stock Investment with Buffett Strategy, Classifier System, Neural Network and Linear Programming .....</b>	<b>255</b>
<b>Analysis of Costs, Benefits and ROI of CRM Implementation .....</b>	<b>261</b>
<b>Comparing Sales Strategies Using the Markov Chain Relationship Model .....</b>	<b>266</b>
<b>Consumers' Trade-Offs of Online Auctions Alternatives -- An Application of Conjoint Analysis .....</b>	<b>272</b>
<b>Cross-Cultural Differences of Online Store Image Perception and Customer Purchasing Intention .....</b>	<b>278</b>
<b>E-Business Adoption in Marketing and its Relationship with Factors in SWOT Analysis: an Empirical Investigation of Small Software Businesses .....</b>	<b>284</b>
<b>Extreme Availability: Determining the Limits of Availability in Commercial Systems.....</b>	<b>290</b>
<b>Impact of Internet Banking on Customer Satisfaction and Loyalty: A Conceptual Model .....</b>	<b>298</b>
<b>Internet Shopping Behavior among Singaporeans: Gender and Educational Issues .....</b>	<b>304</b>
<b>Markov Chain-based Clustering Analysis of Customers and WebPages .....</b>	<b>309</b>
<b>Modeling Competitive Diffusion Process in Japanese ADSL Service Market.....</b>	<b>314</b>
<b>Neural Networks Based Integrated Evaluation Method for the Effectiveness of CRM .....</b>	<b>320</b>
<b>Successful Customer Relationship Management: Antecedents and Imperatives .....</b>	<b>325</b>

<b>Supporting Small Businesses' Penetration of New International Markets - Practitioner's Approach.....</b>	<b>329</b>
<b>The Design of a Lean CRM Software Process Model.....</b>	<b>335</b>
<b>The Development of RFID in Healthcare in Taiwan.....</b>	<b>340</b>
<b>The Glance of an Observer on the War of Brands of Food Products .....</b>	<b>346</b>
<b>Theoretical Framework of Empirical Study on Consumer Behavior in Web-Based Commerce .....</b>	<b>355</b>
<b>Willingness to Pay for Digital Services: Challenges for Future Research .....</b>	<b>359</b>
<b>Working Mechanism and Structure of Customer Services Support System.....</b>	<b>364</b>
<b>A Component-based Framework for Distributed Business Simulations in E-Business Environments .....</b>	<b>370</b>
<b>A Global Perspective of Business Usage of Web Technology .....</b>	<b>376</b>
<b>A Personalized Recommender System Based on Explanation Facilities Using Collaborative Filtering .....</b>	<b>382</b>
<b>A Process Model for Assessing the Distribution Options for Horizontal E-Business Portals ...</b>	<b>388</b>
<b>An Agile Protocol for E-Commerce .....</b>	<b>393</b>
<b>B2B Electronic Markets: A Conceptual Model for Analyzing the Sources of Business Value..</b>	<b>397</b>
<b>Benefit Evaluation Model of E-Government Procurement .....</b>	<b>402</b>
<b>E-Business Value Process Modelling .....</b>	<b>408</b>
<b>Evolution of Service Model and Architecture of ASP Business .....</b>	<b>414</b>
<b>Integrated Optimization Model of Production Planning and Scheduling for Batch Production .....</b>	<b>419</b>
<b>Mapping from BPMN-Formed Business Processes to XPD L Business Processes .....</b>	<b>422</b>
<b>Methodological Approach for Choosing Portfolio of E-Business Models.....</b>	<b>428</b>
<b>Rationality Validation of Business Process Model by Simulation Method .....</b>	<b>435</b>
<b>Research on Mobile Agent-based E-Commerce System Framework .....</b>	<b>440</b>
<b>Towards Collaborative Travel Recommender Systems .....</b>	<b>445</b>
<b>Web Service Based Universal Management of Workflow Resources .....</b>	<b>452</b>
<b>A Comparative Analysis of International and Chinese Electronic Commerce Research .....</b>	<b>460</b>
<b>A Conceptual Framework for E-tailing Quality and Its Evaluation.....</b>	<b>466</b>
<b>A Multi-Agent System for E-Business Processes Monitoring in a Web-Based Environment ...</b>	<b>470</b>
<b>A Study of Competences and Indicators for Electronic Commerce Professional Managers ....</b>	<b>476</b>
<b>A Study of Influencing Traditional Travel Agencies' Decision Making to Introducing B2C E-commerce.....</b>	<b>482</b>
<b>A Value Chain Based Analysis of Electronic Commerce's Transformation of China's Pharmaceutical Industry .....</b>	<b>488</b>
<b>An Exploratory Study of the Electronic Distribution of Hotel Rooms in Europe .....</b>	<b>493</b>
<b>An Initial Study on the Intensifying Enterprises Information Management.....</b>	<b>499</b>
<b>Antecedents of E-Business Assimilation in Manufacturing SMEs.....</b>	<b>505</b>
<b>Business Drivers for Application Servicing and a Software-as-a-Service Model .....</b>	<b>511</b>
<b>Comparison of E-Commerce Practices between Large Enterprises and Small to Medium Enterprises.....</b>	<b>517</b>

<b>Demonstrative Analysis of Hi-tech Enterprises Technology Innovation Capability Based on ISM</b> .....	522
<b>Determinants of E-Cmmerce Adoption in SMEs</b> .....	527
<b>E-business Management System Based on Coordinated Center for Dealer</b> .....	533
<b>E-Business Oriented Optimal Online Auction Design</b> .....	538
<b>Economies of Information Consumer Commodities – An Introduction to Conceptualising Forms of Information Capitalism by Two Cases</b> .....	544
<b>Effective and Strategic Use of Electronic Reverse Auctions</b> .....	550
<b>How E-Ready is E-Sri Lanka?</b> .....	556
<b>Internet Role in Lithuania SMEs internationalization</b> .....	562
<b>Investigating the Use of the Business Model Concept through Interviews</b> .....	568
<b>Logistical Performance as a Key Factor of Success for European Food E-tailers– Three Paradoxes and a Research Agenda</b> .....	574

# The Fourth International Conference on Electronic Business

**Dec 5 ~ 9, 2004**

**Beijing, China**

## **PROGRAMME**

### **SUPPORTED BY:**

National Natural Science Foundation of China  
Science Fund for Creative Research Group

### **HOSTED BY:**

School of Economics and Management, Tsinghua University, Beijing, China  
Research Center for Contemporary Management, Tsinghua University, Beijing, China

# The Fourth International Conference on Electronic Business

Dec 5 ~ 9, 2004, Xiyuan Hotel, Beijing, China

## Program Layout

SUNDAY, DECEMBER 5, 2004				
Ω 14:00-18:00	Registration (The Lobby of Xiyuan Hotel) * Registration will also be arranged on Dec 6, 8:00-12:00 am.			
Ω 19:00-20:00	Reception (Revolving Restaurant)			
MONDAY, DECEMBER 6, 2004				
Ω 9:00-12:00	Plenary Session (the Grand Banquet Room)			
Ω 12:00-13:00	Lunch (Food Street)			
Ω 13:30-15:35	Session M3-R1	Session M3-R2	Session M3-R3	Session M3-R4
Ω 15:35-15:55	Coffee Break			
Ω 15:55-18:00	Session M4-R1	Session M4-R2	Session M4-R3	Session M4-R4
TUESDAY, DECEMBER 7, 2004				
Ω 08:30-10:10	Session T1-R1	Session T1-R2	Session T1-R3	Session T1-R4
Ω 10:10-10:30	Coffee Break			
Ω 10:30-12:10	Session T2-R1	Session T2-R2	Session T2-R3	Session T2-R4
Ω 12:10-13:05	Lunch (Food Street)			
Ω 13:30-15:35	Session T3-R1	Session T3-R2	Session T3-R3	Session T3-R4
Ω 15:35-15:55	Coffee Break			
Ω 15:55-18:00	Session T4-R1	Session T4-R2	Session T4-R3	Session T4-R4
WEDNESDAY, DECEMBER 8, 2004				
Ω 08:30-10:10	Session W1-R1	Session W1-R2	Session W1-R3	Session W1-R4
Ω 10:10-10:30	Coffee Break			
Ω 10:30-12:10	Session W2-R1	Session W2-R2	Session W2-R3	Session W2-R4
Ω 12:10-13:05	Lunch (Food Street)			
Ω 13:30-15:35	Session W3-R1	Session W3-R2	Session W3-R3	Session W3-R4
Ω 15:35-15:55	Coffee Break			
Ω 15:55-18:00	Session W4-R1	Session W4-R2	Session W4-R3	Session W4-R4
Ω 19:00-20:00	Banquet (the Grand Banquet Room)			
THURSDAY, DECEMBER 9, 2004				
08:30: One day tour (OPTIONAL) Registration fee doesn't include the cost for one day tour, participants who plan to join the one day tour need to pay on site. Hotel organize one day trip every day. If you want to join the one day trip, please tell Xiyuan Hotel staff about your one day tour plan when you check in, Hotel staff will guide you to purchase the one day tour ticket. Details about payment and tourist information see Tour Information on our website. line 1: the Forbidden City, the Summer Palace and the Temple of Heaven line 2: The Great Wall, Ming Tombs				

# The Fourth International Conference on Electronic Business

Dec 5 ~ 9, 2004, Xiyuan Hotel, Beijing, China

## Program

### SUNDAY, DECEMBER 5, 2004

Ω 14:00-18:00 Registration (The lobby of Xiyuan Hotel)

\*Registration will also be arranged on Dec 6 8:00-12:00 am.

### MONDAY, DECEMBER 6, 2004

#### Plenary Session

Chair: Jian Chen

Ω 9:00-10:00 Massive Quasi-Experimental Research Methods and the Discovery  
of E-Business Knowledge

**Robert J. Kauffman**

Ω 10:00-10:30 Coffee Break

Chair: Jian Chen

Ω 10:30-11:30 Push-Pull Production: A Model for the Internet Age

**David D. Yao**

Ω 12:00-13:00 Lunch

#### Session M3-R1: SCM (I)

Ω 13:30-15:35 **On Inventory Strategies of Online Retailers**  
**Frank Y. Chen, S. H. Hum, Cheryl H. Sim**

**The Operating Cost in a Tele-working Organization**  
**Xiaojun Li, Pengzhu Zhang, Fanghsin Liu**

**A Study of Benefits of Information Sharing between Production Systems  
and Service Centers**  
**N.Viswanadham, Vijay Desai**

**Supply and Demand Management under Inducement of Price Discounts - A  
Monte Carlo Simulation Analysis**  
**Henry C. Co**

**Coordination Mechanisms in the Supply Chain based on E-business**  
**Suicheng Li, Xianxia Cui, Gongqian Liang**

#### Session M3-R2: Case Study: Regional e-Business

Ω 13:30-15:35 **E-business and Organizational Learning: A Case Study of Three Globally  
Operating Companies**  
**Marjatta Maula**

**Intended Usage of Online Supermarkets: The Singapore Case**  
**Hui Tak Kee, David Wan**

E-Business: Factors of EAI Adoption in an Australian Electricity Company  
Ying Chen, Alex Wong

Exploring the Reality of E-Commerce Benefits among South African Businesses  
Alemayehu Molla

Forecasting the Consumption for Electricity in Taiwan  
Hsiaotien Pao, Tenpao Lee

**Session M3-R3: E-readiness and Regional E-business Strategy (I)**

- Ω 13:30-15:35    **The Analysis of the Difficult Point on Developing E-Commerce of the Western Region in China**

# A Framework to Support Coalition Formation in Supply Chain Collaboration

Chattrakul Sombattheera, Aditya Ghose, Peter Hyland

## ABSTRACT

This paper proposes a framework for agents in globally collaborative supply chain by applying the concept of coalition formation, a cooperation game in game theory. This framework provides mutual benefits to every party involved buyers, sellers and logistics providers. It provides a common gateway that allows individual parties to locate the right partners, negotiate with them, and form coalition in the best possible ways. The framework is applicable to real world e-business models, including B2C, B2B, supply chain and logistics, SME, etc. We firstly discuss common needs existing in today e-business. We then discuss about our framework, i.e., negotiation protocol and decision mechanism.

**Keywords:** coalition formation, game theory, negotiation protocol, decision mechanism

## 1. INTRODUCTION

The current business environment is characterized by large complex supply chains that are often global in reach and that are highly adaptive, being frequently re-configured to respond to dynamic business contexts. It is widely recognized collaboration across the supply chain is a key prerequisite for supply chain efficiency. The effective deployment of information technology and systems, specially the Internet and the worldwide web, has made new modes of complex, dynamic yet effective collaboration possible across supply chains. Collaboration in supply chains can take various forms. Suppliers and buyers might collaborate to increase buying/selling power, to reduce logistics costs or to aggregate capacity. The problem of determining an optimal set of collaborative arrangements/agreements for a given firm can be complex. This research seeks to develop automated (or semi-automated) negotiation protocols as a basis for building decision support functionality for dealing with this complexity.

The coalition formation problem ([4], [9]) considers techniques and criteria that might be used by a collection of (rational) agents to decide how they might group together to improve individual or social utility. Coalitions are ubiquitous in real-life settings. The theoretical underpinnings of approaches to coalition formation lie in the literature on multi-player games in game theory ([9]). Players negotiate among themselves about payoffs to decide which coalition to join. In reality, it is more complex than that. Self-interested agents, operating in dynamic environment such as supply chain, are under heterogeneous constraints. Furthermore, each agent has its own strategies that increase or decrease the value of each constraint thus affects the decision making of agents. A simple example of this is one is using express mail service, which costs more, due to a deadline while another is using ordinary mail service, which costs less, with further deadline. While time is changing in dynamic environment, the

value of a constraint varies thus affecting the utility of the agent. In contrast to traditional coalition formation study, where the coalition value is predefined and thoroughly known among agents, an agent has to calculate, according to its constraints and strategies, for the coalition that would give it maximum utility. We believe that two of the key components of successful coalition formation of self-interested agents are, one, quickly negotiating with other agents and, two, selecting the best possible coalition. Each agent, bounded by its own constraints, may negotiate with others to form a coalition, which is likely to yield maximum benefit. Such a coalition, however, may not be formed due to the constraints. So the agent has to look for the next best possible coalition by consulting with its internal utility mechanism. Negotiation and decision must be done in a timely fashion. There are works in coalition formation that discuss the formation of buyers, sellers and LPs separately. This work provides a basic framework that allows thorough collaboration among agents in supply chain. It includes two important components: a negotiation protocol and a decision mechanism. The negotiation protocol allows agents to exchange necessary information before deciding which coalition to join. A coalition can be as complex as a coalition of buyers, sellers and LPs. **We restrict attention to traditional supply chain activities for the sake of simplicity. Our focus is primarily on material flows, but note that many of the concepts developed in this work could apply equally well to these other forms of collaboration.**

## 2. COLLABORATION IN THE SUPPLY CHAIN

As discussed earlier, our focus in this paper is to develop coalition formation techniques that are appropriate to large, complex supply chains. In our domain, we can conceive of three categories of actors/agents: *buyers*, *sellers* and *logistics providers (LPs)*. In this view, a logistics provider is any organization that provides transportation, warehousing

or other logistics-related services. A firm (buyer or seller) has a set of plans to produce goods. Each plan consists of multiple activities, which may be of two types: *external* and *internal*. External activities are those that involve with *i*) procuring raw materials from external suppliers and *ii*) transporting the raw materials from the suppliers' warehouses to appropriate manufacturing sites. Internal activities are those that deploy internal resources of the firms (e.g., in-house manufacturing, assembly etc.). These activities are often required to satisfy synchronization/scheduling constraints, and there are penalties associated with the violation of these constraints. In addition to these constraints, each agent/actor seeks to satisfy several (internal) objectives, e.g. buying the raw materials at the affordable prices, with acceptable quality etc. In modern web-enabled supply chains, the process of matching buyers with sellers (of goods or services) is often facilitated by online e-marketplaces. Our framework assumes the existence of multiple such e-markets, where sellers advertise their product or service offerings while buyers advertise their requirements. There are many different motivating factors that make firms collaborate. In other words, there are multiple distinct drivers for coalition formation.

The simplest form of a supply chain coalition is one where a buyer forms a coalition with a seller and an LP to satisfy one of the external activities in a plan (e.g. to supply and deliver a manufacturing input to a production process). Buyers sometimes form coalitions with other buyers for the purpose of buy-side aggregation, i.e., the aggregation of buying power. Sellers sometimes form coalitions with other sellers to aggregate selling power. Such coalitions are common for small sellers, such as in agricultural cooperatives (e.g. for micro-producers of dairy products). Logistics provider (LPs) may want to form coalitions to aggregate their service capacities. We note that we have only listed the basic drivers. Most real-life supply chain coalitions tend to have more than one motivating factor driving their formation. Thus a coalition consisting of several sellers and several LPs might be driven by the need to aggregate selling power (for the sellers), the need to aggregate production capabilities (again for the sellers) and the need to offer comprehensive production and delivery contracts (thus bringing in one or more LPs into the coalition). We also note agents/actors (i.e., buyers, sellers or LPs) could participate in more than one coalition at any given point in time. Thus a seller might participate in a coalition with other sellers to aggregate selling power, while simultaneously participating in a coalition with a different set of sellers in order to aggregate manufacturing capabilities.

Both quantitative and qualitative factors play a role in coalition formation decisions. Price, delivery cost and lead time are examples of the former while quality, satisfaction and trust are examples of the latter. In the current work, we focus on four key criteria - cost, lead

time, quality and trust - while acknowledging that other criteria might be relevant (though possibly less important). Cost is the sum of price and delivery cost. Lead time is the time elapsed between an order being placed and the good or service becoming available. Trust is usually taken to denote the degree of belief of an actor/agent that another actor/agent will live up to its commitments. These attributes are not orthogonal, and most decisions typically involve trade-offs between them. One may be willing to pay more for a shorter lead time (or higher quality or higher trust/reliability) and vice versa. One may, in some settings, be willing to accept longer lead times for the purpose of getting higher quality. Several other instances of such trade-off are common, but we do not list them all here. Although negotiation can be either bilateral or multilateral, we can in most instances reduce negotiation to the bilateral case without loss of generality. The simplest scenario is where single agents negotiate, e.g., a buyer with a seller and a buyer with an LP. A buyer can bilaterally negotiate with multiple sellers/LPs at the same time in order to find the best pair of a seller and an LP. The information exchanged is kept private to each agent. A more complex scenario is where multiple agents negotiate. An agent that stands to benefit the most from forming a coalition usually acts as the coalition leader. A coalition leader negotiates bilaterally with multiple agents of its own type (buyer, seller or LP) to establish a sectoral coalition, i.e., a coalition of buyers, or a coalition of sellers, or LPs etc. The object of such negotiation is usually to establish how the coalition value, i.e., the financial benefits of collaboration might be distributed across the members of the coalition.

### 3. A FRAMEWORK FOR SUPPLY CHAIN COALITION FORMATION

In our model, the agents are divided in three groups—the set  $B = \{B_1, B_2, \dots, B_i\}$  of buyers, the set  $S = \{S_1, S_2, \dots, S_j\}$  of sellers, and the set  $L = \{L_1, L_2, \dots, L_k\}$  of LPs. The set  $LOC = \{loc_1, loc_2, \dots, loc_m\}$  is a set of locations where sellers' manufacturing facilities or warehouses and buyers' sites are located. The set  $G = \{G_1, G_2, \dots, G_n\}$  is a set of goods. Each good  $g$  is associated with a load belonging to the set  $LD = \{LD_1, LD_2, \dots, LD_o\}$ , where a load is defined by either weight or volume. The notion of a load as distinct from a good becomes relevant in the context of negotiation with LPs. The sets  $LOC$ ,  $G$  and  $LD$  are common knowledge to all agents. We will assume that each agent (whether a buyer, seller or LP) has access to the following: 1) A history of the prior coalitions that the agent has participated in. 2) A history of what has transpired in the current round of negotiation. 3) An *operations management system*. In the instance of buyers and sellers, these would essentially be some form of production scheduling and optimization system. For LPs, these would be some form of logistics optimization system. The intent is to be able to query the system to obtain quotes that would be used in the process of

negotiation. Thus a seller should be able to query the operations management system by providing the product requirements and the date/time by which the product must be ready (typically a shipping deadline) to obtain a price quote. This quoted price is typically higher for early shipping deadlines (i.e. rush orders) and vice versa. Similarly, an LP should be able to query such a system with details on the loads, origin, destination and delivery deadlines to obtain a price quote to use in negotiation. Once again, rush orders are likely to result in higher price quotes and vice versa. An operations management system is assumed to have access to real-time data about the firm's current business context, and thus provides highly context-sensitive output. We do not discuss the design and implementation of such systems, but note that most firms (especially larger ones) tend to employ some version of these systems.

In the following, we present a simple negotiation protocol to support coalition formation. We first describe some basic assumptions made by the protocol. A message containing fields set to null is treated as a query. An agent replies to a query with an offer made by filling the null fields of the query with proposed values. Agents negotiate by modifying the values of the received offers and sending them back. Agents accept offers by sending acknowledge messages. When a deal is done, agents are obliged to discharge their commitments.

### 3.1 Buyer to Seller and Buyer to LP Negotiation

Direction	Message
B@S	B2S(msg#, buyer, good, totalquantity, quality, (availabletime, origin, quantity), price, expirytime)
B→S	S2B(msg#, seller, good, quality, (availabletime, origin, quantity), price, expirytime)
B@S	B2Sack(msg#)
B→S	S2Back(msg#)
B@L	B2L(msg#, buyer, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)
B→L	L2B(msg#, LP, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)
B@L	B2Lack(msg#)
B→L	L2Back(msg#)

Note: B is the buyer, S is the seller and L is the LP.

Table 1: Buyers' negotiation messages with sellers over buying goods and with LP over delivering goods.

The buyer begins negotiation by sending a message B2S(msg#, buyer, good, quality, (availabletime, origin, quantity), price, expirytime) to sellers asking for a quote for totalquantity units of the good. (availabletime, origin, quantity) is a list of triples, each of which specifies that a certain quantity of the good needs to be picked up from origin at availabletime. If the buyer is contacting the seller for the first time or wants an updated quote, availabletime, origin, quantity and price are set to null (i.e., the buyer does not wish to pre-specify an available-time, the exact location the good is to be sourced from, the quantity to be sourced from that location and the price the seller may wish to

offer). In subsequent messages from the buyer to the seller, the (availabletime, origin, quantity) triples may have non-null values. This is because the seller would have replied to the buyer with a similar list of tuples (see below) indicating that the seller would be able to meet the order by sourcing production from multiple locations with distinct available times. The expirytime provides the seller with a deadline within which it must reply – otherwise the request will be deemed to have expired. Upon receiving the message, each seller consults its operations management system, retrieves the price quote and available time, then replies to the buyer with the message S2B(msg#, seller, good, quality, (availabletime, origin, quantity), price, expirytime), indicating that the seller will be able to offer the good, at a specific price, ready at origin on availabletime. The offer lasts for expirytime (in case the seller is not in a position to supply the good, it will not reply). If the buyer is satisfied with the offer, it will send the message B2Sack(msg#) back to the seller. Once the seller receives it, the deal is done—the buyer is obliged to pay money and the seller has to supply the good. If the buyer is not satisfied with the price, it negotiates on the price by sending the message B2S(msg#, buyer, good, quality, (availabletime, origin, quantity), price, expirytime) with the new price back to the seller again. If the seller is satisfied with it, it will send the message S2Back(msg#) back to buyer in order to seal the deal.

At the same time, the buyer also contacts one or more LPs to organize shipping of the product. It sends the message B2L(msg#, buyer, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime) to LPs. The (load, quantity, origin, destination, pickuptime, arrivaltime) is a list of packaging tuples, each of which specifies that there are quantity of loads to be picked up from origin at pickuptime and to be delivered to destination at arrivaltime. For the first message from a buyer to an LP, or when the buyer seeks an updated quote, the cost will be set to null. Upon receiving the message, the LP consults its operations management system to compute the cost of the delivery job. It then sends the quote to the buyer with the message L2B(msg#, LP, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime). The quote will last for expirytime. If the buyer is satisfied with the quote, it finalises the deal by sending the message B2Lack(msg#) back to the LP. If the buyer seeks to make a counter-offer to an LP, it will set load, quantity, origin, destination, pickuptime, arrivaltime and cost to its desired values. It then sends a message B2L(msg#, buyer, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime) to the LP. If the LP is happy with it, it will reply with the message L2Back(msg#). Both buyer and LP are now contracted.

### 3.2 Decision Mechanism

At the top level, buyers have to obey a set of criteria in order to make decisions about their external activities.

We modify multi-attribute decision making scheme proposed by Keeney and Raiffa ([7]). Instead of having a fixed weight attached to each attribute, we propose to have a dynamic weight table for each attribute. The dynamic weight table associates a set of weights with a number of environment conditions in one-to-one manner. The environment conditions are the facts, which affect the weight, or importance, of an attribute. For example, the weight for time and price are equal to 1 in normal situation. In the face of a shortage of a raw material, the weight of time is 10 times more than that of the price. The environment conditions can be achieved from internal or external sources. They can be in form of relation among attributes and facts. Therefore, the near optimal is acceptable to experienced agents who know how to make good profit in the long run.

Strategic weight

Condition	Attribute	Weight
$X_1$	$a_1$	$w_{11}$
$X_2$	$a_1$	$w_{12}$
$X_1$	$a_2$	$w_{21}$
$X_2$	$a_2$	$w_{22}$

$$U = \sum_{q=1}^n w_{qp} a_q \text{ Where condition } X_p \text{ holds}$$

Buyer's ranking table

Sellers' offers	LPs' offers	$\sum_{q=1}^n a_q w_{qp}$
(msg <sub>1</sub> , S <sub>1</sub> )	(msg <sub>7</sub> , L <sub>7</sub> )	$\sum_{q=1}^n a_q w_{qp} + \sum_{q=1}^n a_q w_{qp}$
(msg <sub>2</sub> , S <sub>1</sub> )	(msg <sub>8</sub> , L <sub>8</sub> )	$\sum_{q=1}^n a_q w_{qp} + \sum_{q=1}^n a_q w_{qp}$
(msg <sub>3</sub> , S <sub>2</sub> )	(msg <sub>9</sub> , L <sub>8</sub> )	$\sum_{q=1}^n a_q w_{qp} + \sum_{q=1}^n a_q w_{qp}$

Figure 1: Strategic weight table, utility calculation and ranking for the best combination of seller and LP.

Each agent maintains the strategic weight table, which counsels the agent a value of the weight of an attribute under a certain condition. The weight of an attribute is in a range of integer numbers. The agent controls values of the lower and upper bounds. A condition change can be a stock shortage, a financial concern, a complaint from customer, or a combination of them. An agent learns from its experience that how the changing environment affects its business and how to react. The results of the reactions will be analysed by the agent and it will update the range of the weights and their values under such conditions. It specifies in the table about a certain condition  $X_p$  expressively. Each attribute  $a_q$  affected by the condition  $X_p$  will be assigned a specific weight  $w_{iq}$  to it. For example, when "there is a stock shortage of a raw material g" (good  $g \in G$ ), the weight of the attribute "price" under this condition will be decreased while the weight of lead time will be increased. The agent updates its strategic weight table every time it senses a change in environment. This allows agent to act wisely in dynamic environment. Among the four attributes, trust is a special decision criterion in the sense that it depends on other attributes such as time and quality promised by other agents. Agents maintain trust differently. Each buyer has a trust table keeping record of other agents, including other buyers, sellers and LPs, and their trusted values. Each agent in the trust agent is associated with an integer value from range  $[-1, 1]$ . The value is updated over times.

When a buyer is dealing with a new agent, it may give a low value to trust, e.g. 0.3 or 0.4 to the new agent. If the agent performs well, e.g., keeps up with schedule, provide high quality of good, etc., the buyer increases trust value for that agent. On the other hand, if an agent fails to keep up with its promise, the buyer decreases the trust value. All the offers made by sellers and LPs are kept in buyers' knowledge base. Whenever it needs to compute the utility, it checks for the current environment condition  $X_p$  and take the corresponding weight  $w_{pq}$  of each attribute  $a_q$ . It creates a new tuple (msg#, agent) for each active offer and create a new ranking table composed of three fields: sellers' offer (msg#, agent), LPs' offers (msg#, agent) and  $\sum_{q=1}^n a_q w_{qp}$ . The first two fields are merely reference to the exact offers. The third field is the utility for each combination of sellers and LPs offers. The agent computes the utility for each combination by combining utility of the seller's offer and that of the LP's offer. The utility of an offer can be achieved by  $\sum_{q=1}^n a_q w_{qp}$ , where  $a_q$  is the attribute value retrieved from the corresponding offer, and  $w_{pq}$  is the weight of the attribute  $a_q$  under condition  $X_p$ .

### 3.3 Buyer to Buyer Negotiation

Direction	Message
Bl@Bm	Bl2Bm(msg#, buyer, good, quality, (availabletime, origin, quantity), price, expirytime)
Bl~Bm	Bm2Bl(msg#, buyer, good, quality, (availabletime, origin, quantity), price, expirytime)
Bl@Bm	Bl2BmDel(msg#, buyer, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)
Bl~Bm	Bm2BlDel(msg#, buyer, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)
Bl@Bm	Bl2BmAck(msg#)
Bl~Bm	Bm2BlAck(msg#)
Bl@Bm	Bl2BmDelAck(msg#)
Bl~Bm	Bm2BlDelAck(msg#)

Note: Bl is the leading buyer, Bm is a member buyer.

Table 2: Buyers' negotiation messages on buying goods.

Buyers can form coalition to share discount on prices and delivery costs. A buyer can join any appropriate coalition. A buyer can join a coalition for discount on price and join another coalition for saving delivery cost. This allows agents to maximise benefits freely. When a buyer wants to form a coalition of buyers, it becomes a leading buyer, who tries to negotiate among buyers to form a buying coalition then negotiates on behalf of the coalition to agree on the prices with sellers. Firstly, the leading agent consults with its knowledge about other buyers who might be interested. Agents are considered being interested if i) they used to buy the same good at around this time previously, ii) they are located nearby, or iii) randomly selected. The leading agent sends the message Bl2Bm(msg#, buyer, good, quality, (availabletime, origin, quantity), price, expirytime) with value of origin, quantity and price set to null to all interested agents. The interested agents consider the invitation and if they find that they are in need of the same good of the same quality at availabletime, they will reply by sending the message Bm2Bl(msg#, buyer, good, quality, (availabletime, origin, quantity), price,

*expirytime*) with the *quantity* set to an appropriate value back to the leading buyer. After the expiry time, the leading buyer assumes that all the truly interested buyers have responded. It then sums up all the *quantities* and sends the message *B2S(msg#, buyer, good, quality, (availabletime, origin, quantity), price, expirytime)* to sellers. The sellers will reply with the message *S2B(msg#, seller, good, quality, (availabletime, origin, quantity), price, expirytime)*.

Upon receiving quotes from sellers, the leading buyer select the one with maximal utility, computed the same way discussed above. It then computes the price for each interested agents. Then the leading agent sends the message *Bl2Bm(msg#, buyer, good, quality, (availabletime, origin, quantity), price, expirytime)* to interested agents. If the all interested agents agree, they send the message *Bm2BlAck(msg#)* and the coalition is formed. If any of them is not satisfied with the share, they may negotiate on the price by sending message *Bm2Bl(msg#, buyer, good, quality, (availabletime, origin, quantity), price, expirytime)*. The leading buyer may try to satisfy the demanding buyers by giving away its share on the discount (Kraus et al., 2004) up to a limit. Whenever it goes beyond that, the leading buyer send the message *B2S(msg#, buyer, good, quality, (availabletime, origin, quantity), price, expirytime)* with the price increased by the excess to the seller. If the seller accepts it, the leading buyer sends the *Bl2BmAck(msg#)* to all members. The buying coalition is now formed. All members are obliged to pay the bills. If the seller does not accept, the negotiation goes on, virtually similar to that between a single buyer to a single seller. If the time runs out, then all of them suffer loosing opportunity.

Any buyer can try to manage transportation for other agents. Those agents may have been already interested in buying within the same buying coalition or may be located nearby. The process is similar to forming buying coalition. The leading buyer sends message *Bl2BmDel(msg#, buyer, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)* with *load, quantity* and *cost* set to null to all interested agents. The recipient agents consider if the *origin, destination, pickuptime*, and *arrivaltime* are suitable with their plans. The interested agents sent message *Bm2BlDel(msg#, buyer, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)* with *(load, quantity, origin, destination, pickuptime, arrivaltime)* and *cost* set to appropriate values back to the leading buyer. The leading buyer collects all replies and send message *B2L(msg#, buyer, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)* with *(load, quantity, origin, destination, pickuptime, arrivaltime)* set to all members' requests and *cost* set to null to LPs. The LPs reply with message *L2B(msg#, LP, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)* with *cost* set to appropriate value. The leading buyer computes for

the best offer and compute for the cost for each interested agent. It then sends to interested agents the message *Bl2BmDel(msg#, buyer, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)* with *cost* set to their costs. If all the interested agents are happy with their costs, they reply with message *Bm2BlDelAck(msg#)*. The leading buyer sends the acknowledge message to the LP. The deal is done. If the interested agents are not satisfied with their costs, they negotiate with the leading agent by sending message *Bm2BlDel(msg#, buyer, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)* with their preferred *costs*. The leading agent can try to negotiate with the unhappy buyers by giving away its share on the saved cost up to a threshold. If the demanding goes beyond the threshold, the leading buyer negotiates with the LP. The process repeats backward and forward until every agent is satisfied or the time expires.

### 3.4 Seller to Seller and LP to LP Negotiation

Sellers can form coalition when appropriate. Once a seller receives a quote it considers out of its resources or considers outsourcing is beneficial, it negotiates with other sellers. It firstly consults with its own plan for its capability and consults with its knowledge base for outsourcing to other sellers. It computes for other sellers' share on goods and prices. It sends message *Sl2Sm(msg#, seller, good, quality, availabletime, quantity, price, expirytime)* with *price* set to null to other sellers who can mutually cover the outsourcing. The recipients reply with the *prices*-quoted message *Sm2Sl(msg#, seller, good, quality, availabletime, quantity, price, expirytime)*. If the leading seller is satisfied with all quotes, its finalises the deals with other agents by sending message *Sl2SmAck(msg#)*. If it is not satisfied with any of them, it can negotiate, similarly to how the leading buyer does it. Once all of the unsatisfied agents agree, they accept by sending message *Sm2SlAck(msg#)* back to the leader. Then the deal is done.

Direction	Message
<i>Sl@Sm</i>	<i>Sl2Sm(msg#, seller, good, quality, availabletime, quantity, price, expirytime)</i>
<i>Sl-Sm</i>	<i>Sm2Sl(msg#, seller, good, quality, availabletime, quantity, price, expirytime)</i>
<i>Ll@Lm</i>	<i>Ll2Lm(msg#, LP, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)</i>
<i>Ll-Lm</i>	<i>Lm2Ll(msg#, LP, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)</i>
<i>Sl@Sm</i>	<i>Sl2SmAck(msg#)</i>
<i>Sl-Sm</i>	<i>Sm2SlAck(msg#)</i>
<i>Ll@Lm</i>	<i>Ll2LmAck(msg#)</i>
<i>Ll-Lm</i>	<i>Lm2LlAck(msg#)</i>
Note: <i>Sl</i> is the leading seller, <i>Sm</i> is a member seller. <i>Ll</i> is leading LP, <i>Lm</i> is member LP.	

Table 3: Sellers' negotiation messages over selling goods and LPs' negotiation messages over delivery jobs.

When contacted from either a buyer or a seller, an LP may form coalition with others when it does not have

enough resources or it finds that forming coalition is more profitable. The leading LP may divide whole distribution area into sections and decide to bilaterally negotiate with LPs, each of which is considered having enough potential to distribute the good on assigned section. The leading LP sends message *L12Lm(msg#, LP, (load, quantity, origin, destination, pickuptime, arrivaltime), cost, expirytime)* with *(load, quantity, origin, destination, pickuptime, arrivaltime)* set to calculated values to potential agents. Each member agent tries to accommodate the on-negotiating job with its own resources and its on-going plans. If the member is satisfied with the offer, it sends message *Lm2LLAck(msg#)* back to the leading LP—the deal is done. If not, it negotiates with the leading LP similar to buyers and sellers. Some LPs may not be satisfied with bilateral negotiation, they may force the leading LP to manage the multilateral negotiation for the sake of fairness and efficiency. LP negotiation is concerned with the cost of doing the job and the profit. The cost is involved with the route a LP run regularly and the route for the new job.

#### 4. RELATED WORK

Coalition formation is an active research area in multi-agent systems. Previous work has done some part of our proposing framework as the followings. Li et al. ([8]) addressed the combinatorial auction in coalition formation. Buyers submit their requests to the mediator who will allocate the good from sellers to them. Goldman et al. ([2]) searched for a strategy where sellers selected the most profitable deal while buyers looked for the most satisfiable sellers. Kraus et al. ([6]) proposed a compromise strategy for distributing profits among sellers in order to form coalition quickly. They found that agents who are willing to give away their profits actually earn more. Breban et al. ([1]) addressed the coalition formation based on trust among agents. Trust is used as a mechanism to enforce agents to commit themselves to the jobs as parts of the coalition. Hyodo et al. ([3]) addressed the optimal coalitions of buyers and sellers who are located in distributed sites. They deploy genetic algorithm to search for the optimal share over the discount. Klusch et al. ([5]) addressed problems in static coalition formation and proposed an algorithm for mobile agents to form coalition under dynamic environment. Agents can form overlapping coalitions.

#### 5. CONCLUSION AND FUTURE WORK

We propose a simple framework, which involves negotiation protocol and decision mechanism. The negotiation protocol allows thorough communication, i.e., buyers to buyers, buyers to sellers, sellers to sellers,

buyer to LPs, and LPs to LPs. The decision mechanism is a modification of Keeney et al.'s ([7]), which allows agents to adapt its decision to suit with changing environment. Agents can select appropriate weights for the environment in order to make suitable decision. The traditional utility-based decision mechanism seems inadequate in complex settings in real world. New approaches, e.g., Markov decision processes, Bayesian networks, CPNets, are suitable for more complex and dynamic environment. Under uncertain environment, agents have to learn from the past and project it to forecast what will happen in the future. Efficient utilization of knowledge base should help agents perform better in dynamic coalition formation. Based on this framework, we want to develop agents who are able to evolve strategies in order to enhance cooperation. Instead of modeling supply chain competitive games, we want to explore that under changing environment, how agents can adapt their strategies to cooperate and be successful at the end.

## ABSTRACT

Integrated Manufacturing and Service Networks (IMSNs) are an assemblage of companies formed with the primary goal of delivering value in terms of both goods and services to the customer through out the product life cycle - from cradle to the grave. Manufacturing-service integration will lead to information sharing between design, manufacturing and sales units of the manufacturer and the service centres. While the integration between design and manufacturing is very well studied, the subject of collaboration between manufacturing units and service centre received practically no attention.

In this paper, we present two models each with increasing complexity to elucidate the benefits of integration and alert against problems like bullwhip effect percolating from supply chains into IMSN. The first one is a conceptual model that captures the relationship between manufacturing and service networks and makes a case for coordination between the two entities. The second model, IMSN with single product, evidences the benefits of collaboration in a more realistic setting.

In all the above models, we make use of cause effect diagrams and system dynamic models to study the benefits of integration. We study the effect of reactive (feedback) and also the proactive (feedforward) use of information for service centre resource management.

**KeyWords:** Manufacturing, Service, Bullwhip effect, Service Center Design.

## 1. INTRODUCTION

Integrated Manufacturing and Service Networks (IMSNs) are an assemblage of companies formed with the primary goal of delivering value in terms of both goods and services to the customer through out the product life cycle - from cradle to the grave. The product life cycle could be divided into design, manufacturing and service phases. During the design phase, collaborative teams design products taking into account the manufacturability, logistics requirements, ease in assembly, ease in fault diagnosis and the serviceability. The manufacturing phase involves procurement, manufacturing, distribution and sales. The service phase comprises of activities like preventive maintenance, testing and fault diagnosis, repair services, call centres and emergency services.

There is lot of interaction between the production phase and service phase, which has not been given attention. For example, a company which considers service phase in design and manufacturing phase can introduce onboard diagnostics for monitoring machine health and proactive maintenance to provide failure free performance. *It is estimated that reactive maintenance costs over six times more as compared to proactive maintenance and leads to increased customer satisfaction.* Expert system software combined with strategically located sensors and transducers (e.g., pressure, temperature, vibration, viscosity, wear debris,

and moisture) will provide comprehensive machine health monitoring and as a result making the whole process more efficient.

Every product sold is a potential source of revenue through sales of spare parts and after-sale services such as repair, maintenance and the upgrades. Consumers are demanding better service and OEMs are realizing the importance of providing good service. A recent GM study reported that \$9 billion in *after-sale revenue* yielded \$2 billion in profits. On the other hand, for producing \$2 billion profit from product sales GM will have to sell cars worth \$150 billion. In the sale of products and gaining customer loyalty, after sales service has become a significant factor. Decisions made during design and manufacturing phases affects the performance and cost of service phase. On the other hand, providing good service will boost the product sales. Feedback from service to design will help produce more reliable products. It is thus important to consider the maintenance, fault diagnosis, reparability and serviceability aspects in addition to manufacturability at the design stage.

With OEMs taking a more proactive role in service, they will have a better idea of customers needs. For example, most auto makers have relatively few opportunities to interact with car owners; most of the "touches" they do experience are indirect (through independent dealerships) and occur in less-than-happy circumstances (for example,

when repairs are needed or a vehicle recall is required). Getting involved in service would provide first-hand information of the problems that arise in service and a quick feedback all the way to the design/manufacturing phase for possible pre-emption.

In this paper, we study the benefits of manufacturing-service integration. More specifically, we want to quantify the benefits of information sharing between design, manufacturing and sales units of the OEM and the service centres. The vehicle for our study is the system dynamic models. We develop a cause effect diagram for conceptual model and single product model.

It is known that manufacturing systems are discrete event dynamical systems and so are service networks. Together, they form large discrete event networks. But events in manufacturing system occur at much faster rate than in service networks. The production rates are generally much faster than failure rates. For example, an automobile is manufactured in days but it may not go for servicing for months. Also, while designing IMSN one should be cautious about bullwhip effect in the integrated system which could lead to service system exhibiting oscillatory behavior in its resources: repair crews, spare parts, etc. Our study here using system dynamic models demonstrates the benefits of:

1. Use of service centre feedback in product design to improve both the serviceability as well as reliability.
2. Use of marketing and sales information in reducing bull whip effect in service centre resources.
3. Use of service level or service quality feedback to improve the sales.

In this sense, our study here is a significant contribution to the literature on design – manufacturing – service networks.

## 2. LITERATURE SURVEY

In scanning the literature on IMSN, one has to search from various angles. From the consumer's angle, there are lots of white papers and reports from Accenture and Mckinsey on the benefits of selling solutions rather than products [3, 6, 9, 10]. It is now established through various surveys that profit margins in service are much higher than in product sales. For certain types of industrial equipment such as heavy machines, aircraft engines, etc service is integral part of product sales proposition. Pricing of services, products and product services bundles is an important issue.

From the economic point of view there have been studies on the importance of manufacturing in service economy [7, 8]. There are two other viewpoints, which are important in practice and implementation, the product life cycle and the business process integration viewpoints. The supply chain limits itself to the point of sale of product, which needs to be overcome by integrating the service phase: physically, informationally and organizationally.

As is known, the product goes through the design, production, customer use, service and finally disassembly, reuse and disposal. Most attention in Product Lifecycle (PLC) is given to the direct chain of events i.e. from the design to the customer but the service and recycling are not integrated into other phases of PLC. In service literature, preventive maintenance [12], the repairman problem [12], spare parts management [1, 11] have received lot of attention. Queueing theory, discrete-event simulation and mathematical optimization techniques are widely used to study these problems. Cohen et al [4] build a product life-cycle model to study a set of strategic choices facing the manufacturer of durable good as he designs the joint product/service bundle. They adopt a competitive (as opposed to single-firm optimization) framework, where there is competition for the provision of after-sales service between the manufacturer and an independent service operator. The product price and service quality/price are characterized by equilibrium to a sequential game. Cohen et al. [5] report on a benchmarking study of 14 companies in electronics, computing and communication industries. They observe that after-sales service revenues constitute 30% of product sales revenues. Optimization of field service operations has received attention in the business literature [2].

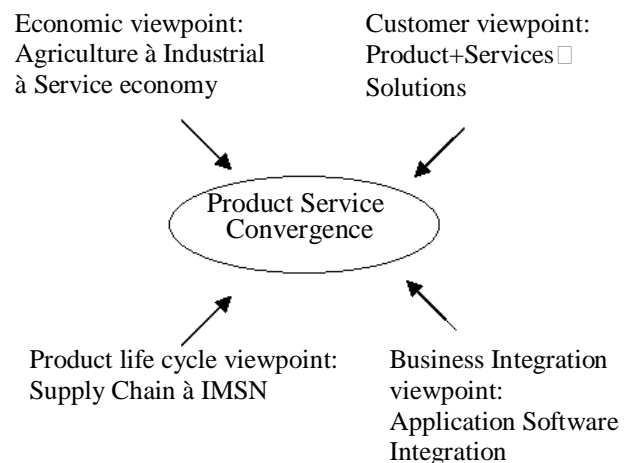

Figure 1: Perspectives on Product Service Convergence

Our attention here is on showing the benefits of sharing information between OEMs and the service providers in terms of improvement in service levels and better service capacity planning.

## 3. MODEL DESCRIPTION

We consider manufacturing–service network for a complex product with one manufacturing company and several geographically distributed service centres as shown in figure 2.

The manufacturer designs the product, produces it and sells the same to a pool of customers. The product could be automobiles, agriculture equipment like tractors, medical equipment, aircraft engines, ink jet printers, etc.

The common feature is they are all durable products that require after sales support for preventive maintenance, spare parts and also breakdown servicing. Three kinds of maintenance and repair services are possible: self service performed by the customer with on-line help, preventive maintenance where the product performance is monitored by in built diagnostics or by periodic checks, and breakdown service generally conducted by the service centre. The breakdown service could be either major or minor and the repair time depends on the type of failure. The repair centre has generally the following physical resources: repair crew, disassembly tools, diagnostic equipment, and spare parts. The customer interface of the repair centre is through a call centre or help desk. The informational resources include the data base containing equipment history, types of problems reported for this equipment as well as similar ones installed elsewhere, the knowledge from the crew reports, etc. The data base also may contain information on the spare parts, and can access the CAD designs and the manufacturing data if needed. The resources of the service centre determine the service levels such as the delivery time and the quality of service etc. The service quality as well as the service centre profitability is monitored for possible improvement. The service centre capacity consists of the physical and human resources and this can be changed by hiring or firing the repair men. In this study we assume that the repair centre capacity can be increased with a delay of three months and decreased as and when necessary. Transferring the regional sales information to service centre would help them increase the service capacity in timely manner.

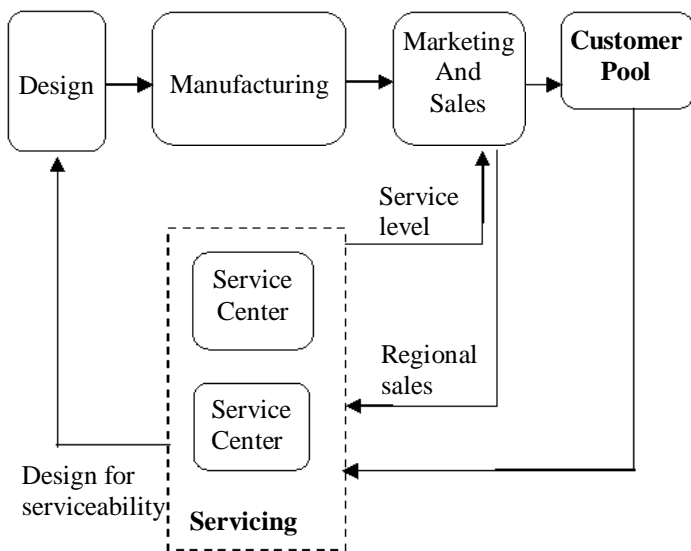

Figure 2: A typical manufacturing-service network

It is known from the literature that after sales service quality influences the product sales particularly from the past customers. We incorporate this in to our system dynamic model by making the service quality as a variable influencing the product sales. Also, the service centre and product design interaction can lead to design

of high reliability products, products with fault diagnostic features, modular products with ease in serviceability etc. We use a utility function to show the positive influence of the service levels on product design which will result in more product sales.

Information exchange between design, service centre and marketing and sales will lead to improvement in the performance of system by bringing coordination. Service centre resource planning will be enhanced by information about regional sales. Similarly, service levels provided by repair centre will improve the sales forecasts of marketing department. We will present three models to demonstrate this.

#### 4. CONCEPTUAL MODEL

We first present a simple model to show benefits of manufacturing, marketing and service centre collaboration. The model demonstrates that sharing information between manufacturing and service phases can have a huge impact on the performance of the system. The simple manufacturer-service network with elements: production, population, sales, service level, repairs, etc. is considered here for illustration. The cause-effect diagram for this is shown in figure 3.

Goods are produced at a constant rate and sales take place according to the utility function. Excess goods produced are inventoried and sold goods enter the population. Whenever a product fails, they come for repairs and service centre makes use of service capacity to perform the repairs. As the population of sold goods increases, more number of products comes for repair and the service capacity needs to be synchronized with population growth to maintain quality of service. Loop 1 in figure 3 shows that as the population increases, there will be more number of products for repair. This would in turn lead to lower service levels and lower the product sales. The service level can be maintained by controlling service capacity in appropriate manner. We explore two mechanisms for controlling service centre capacity in order to maintain the required service level:

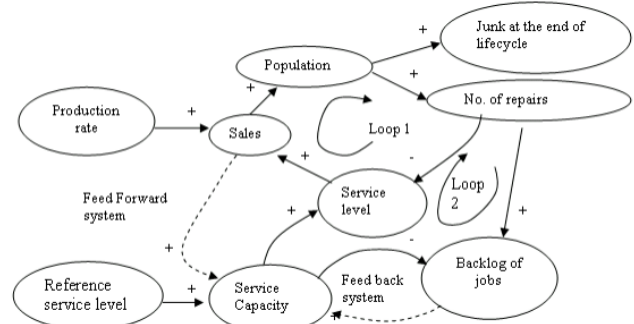

Figure 3: Cause-Effect diagram for Conceptual Model

1. **Feedback system:** Loop 2 is the feedback loop that reduces the backlog of jobs. Whenever jobs get accumulated for repair, the service capacity procurement process is initiated. The new capacity arrives after a fixed

lead time from the time an order is placed. This is the reactive, feedback system and most service centres would typically operate in this fashion when they have no information about product sales. The equation used by the feedback system for capacity requisition is:

$$\text{Capacity ordered on any day} = (\text{Rate of arrival of new jobs}) * 1.1 + (\text{Backlog of jobs}) / 5 - \text{Existing Capacity} - \text{Capacity in the process of procurement}$$

Everyday the service centre is checked for overcapacity and excess capacity is removed according to the following equation:

$$\text{Amount of capacity freed} = \text{Current Capacity} - 1.2 * (\text{Job arrival rate}) - \text{Backlog}$$

2. **Feedforward system:** Sales information can be used to forecast the growth in population and calculate the incremental service capacity required to support the added population. Taking into account the lead-time in procurement of capacity we can ensure timely increase in service capacity. Information visibility that comes with IMSN allows us to have feedforward control to add the service capacity.

We have assumed the lead time to be 120 days and every 120 days we forecast the population growth. The required extra capacity is the population growth multiplied by the failure rate.

$$\text{Capacity ordered every 120 days} = \text{Population growth in 120 days} * \text{Failure rate}$$

Overcapacity is removed according to the following equation:

$$\text{Amount of capacity freed} = \text{Current Capacity} - 1.2 * (\text{Job arrival rate}) - \text{Backlog} - \text{Capacity to support expected population growth}$$

The dotted arrows in figure 3 indicate the feedback and feedforward mechanisms in the cause-effect diagram. We use the cause-effect diagram in figure 3 and Ithink software to simulate the system dynamic model. We assume the following values:

1. A production rate of 1000 units/day is assumed.
2. Car life = 10yrs or 3650 days
3. The service level is the only factor that influences the sales.  $\text{Product Sales} = (\text{Mean\_Service\_level} - 0.7) * 10000 / 3$ .
4. Mean number of failure per day =  $0.01 * \text{Population}$
5. Acquisition of service capacity takes 120 days because of the delays involved in hiring and training.
6. We assume the product life-cycle to be 10 years long.
7. For performing one repair job, one unit of capacity is engaged for a day.
8. Service level for a particular day is the ratio of number of repairs completed in that day to total number of jobs to be completed (including the backlog jobs). Since the number of repairs completed is at most equal to

the capacity,  $\text{Service level} = \text{Min} (\text{Capacity} / \text{Total number of failures}, 1)$ .

Under the above assumptions, the ideal service centre capacity = mean number of failures =  $0.01 * \text{Population}$   
We simulate both feedback and feedforward strategies outlined above.

Feedback system (system 1) responds to accumulation of jobs by increasing the service centre capacity. Since there is a delay in acquiring service capacity and making it operational, in the interim period, the service level declines and jobs accumulate. To clear this up quickly, excess capacity needs to be hired. Thus the reactive feedback system creates a bull whip effect: a sudden increase in product sales will after a lag create a need for excess service capacity. Because of the set up times involved in increasing the service centre capacity, the service levels decline bringing down the sales. This is clear from figure 4. The kind of fluctuations in the service capacity shown in the figure can be prevented by collaboration between the manufacturing and the service centre.

Figure 5 compares the two systems: 1) System with only feedback. 2) System with both feed forward and feedback. The feed-forward system is able to maintain very high service levels while the feedback system shows fluctuations. This is because feed-forward system accurately predicts the required capacity and adds it taking into account the lead time.

On the other hand, feedback system shows considerable variation in the service level, which in turn effects the population growth. The graph in figure 4 illustrates the significant benefits. We observe that because of the high service level, the population in system 2 has more sales than system 1, which is reflected in the populations of the corresponding systems.

An IMSN based on a feedback mechanism responds to the accumulation of jobs by increasing the service center capacity. However since there is an inherent delay in acquiring and deploying service capacity, the impact of service capacity addition is not immediate. Consequentially the service levels continue to decline and jobs continue to accumulate in the interim period. Hence, to rapidly clear the backlog of jobs and to bring the service up to the desired levels, sometimes more capacity than required needs to be added. Thus the reactive feedback system results in a bull whip effect: *a sudden increase in product sales after a lag creates a need for excess service capacity*. Because of the leadtimes involved in service capacity addition, the service centres are unable to maintain their service levels and accordingly the sales decline as shown in Figure 4. The fluctuations in service capacity observed in the system (as shown in Figure 4) can be prevented by promoting collaboration between the manufacturing, sales and the service operations of the IMSN.

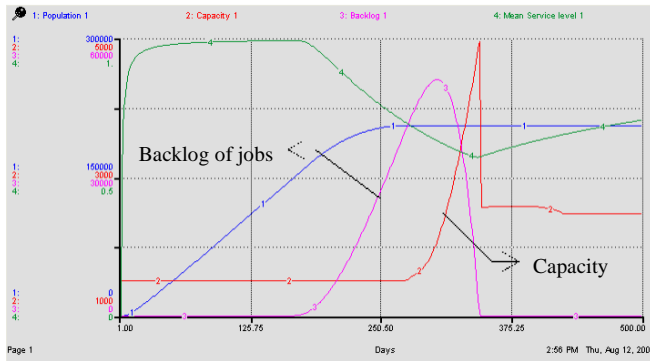

Figure 4: Buildup in service capacity to clear accumulated jobs

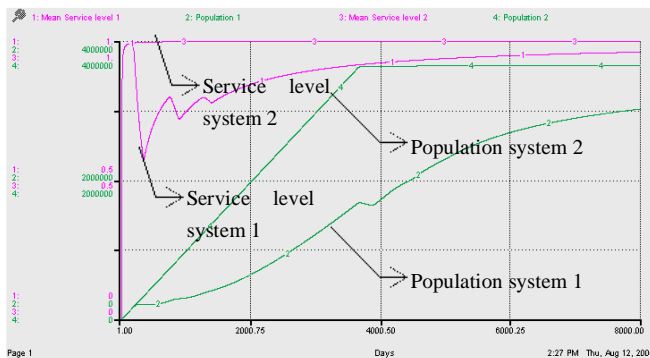

Figure 5: System with Feed-forward and Feedback maintain higher service level than system with only feedback

## 5. MODELING IMSNS WITH A SINGLE PRODUCT

The basic model presented in Section 4 is simplistic in its assumption that the consumer's decision to buy a product is based primarily on the quality of the service. However, in reality the purchase decision is influenced by multiple factors such as the price and quality of both the product and the service and the quality and length of the warranty period. In this section we attempt to incorporate these features into a more realistic model of an IMSN that manufactures and services a single product.

For our analysis we assume that the utility of a product to a consumer is a linear function of product price and quality, service price and quality and the length of the warranty period.

$$\text{Utility} = -\text{Product price} + 1000 \times \text{Product quality} - \text{Service price} + 1000 \times \text{Service level} + \text{Free service contract}.$$

Product price and service price have a negative influence on the utility function since higher prices deter customers from buying the product. Similarly, free service contract periods, better product and service qualities, have a positive influence on the utility as perceived by customers. Furthermore, we also incorporate a reference utility function, similar to the utility described above, which defines a target utility level for the company to aspire towards. In reality this reference utility is

equivalent to the utility of the products offered by the competitors. In this manner we are able to account for competitive pressures facing an IMSN. The reference utility level also provides a goal for the company to work towards, by improving the product and service value proposition. As can be expected, the better the product offered by the IMSN, relative to the competition, higher its sales. Hence, the number of sales that take place in a day is directly proportional to the difference between the reference utility (utility of competitive offerings) and utility of the product offered by the IMSN. If a product service bundle offers superior value the demand for the product will expectedly increase. However increased sales and growth in the product population will over time result in more service demands putting a strain on service levels and quality, requiring some kind of monitoring process to remedy the service deterioration. The influence diagram for an IMSN manufacturing and servicing a single product under the above operating assumptions is presented in Figure 9.

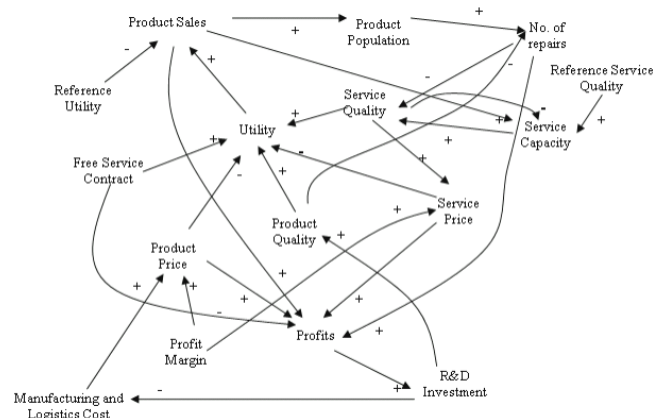

Figure 9: Influence diagram for IMSN with single product

The profits of the IMSN are derived from the sales of both products and services, less the cost of production, service provision and cost of providing free services during warranty. In addition, we assume that a fixed percentage of the profits are continually invested in R&D. These investments bear fruit at a later time in the form of improved product quality, reliability and reduced product prices, in turn stimulating further sales and profits. Concurrently, as the product quality improves, the reliability of the product increases and the number of failure events and consequentially repairs is reduced. In this manner, the concept of design for serviceability is included in our model of an IMSN. However for the sake of simplicity, we have assumed aggregated models for service centres, each of which are geographically distributed. One key differentiating factor in the extended model presented in this section, as compared to our earlier analysis, is the assumption that the product failure rate increases with the age of the product. With an increase in product sales over time the population grows at a higher rate, resulting in greater number of repair jobs. Also, as a product gets old it comes more often for repair. Hence, to predict the load on the service centre we need

to track both product sales and the age of the installed base.

Additionally, we incorporate the feedforward and feedback mechanisms, explained in the earlier sections, for controlling the interaction between the manufacturing and service sectors and for ensuring that service levels are maintained at the required level. For example, in a feedback based system, if the service level drops below the reference service level, service capacity is added. On the other hand, in a feedforward system, the sales data is employed to forecast and plan for additional capacity requirement.

The above model was simulated in IThink to demonstrate that the feed-forward system is better than the feedback system in terms of its ability to improve service levels and the bottom-line for the IMSN. For the simulation study, it was assumed that the lead time for service capacity addition was 120 days and the initial capacity was set to be adequate to meet all demands occurring in the first 120 days of operations. Based on growth of the population and age of installed base a forecast is made for number of failures per day after 240 days and the required extra capacity is added as appropriate. From the influence diagram it may be noticed that the dynamics within this extended and realistic model are more intricate than the basic model presented in Section 4 (Figure 3), establishing the fact that it is harder to predict the behavior of realistic IMSN models. Our analysis was based on the following parameters and assumptions.

1. One unit of service capacity costs 100 units of money per period.
2. The price charged for service dependent on the service level offered as dictated by the following relationship.  

$$\text{Service Price} = \text{Service capacity cost} * (1 + \text{service level}).$$
3. Profit margin of 10% incorporated in the price of products
4. Product quality & Manufacturing cost improves non-linearly for incremental investments in R&D, meaning that the ROI for R&D investments is more than 100%.
5. The probability of a product failing increases over time.
6. The product becomes obsolete in 6 years, in a non-linear manner, as it rapidly becomes outdated in its first few days before being gradually replaced over time.

The service levels for IMSNs with only feed-back and with both feed-back and feedforward were simulated and compared as shown in Figure 10. Clearly an IMSN with feedforward and feedback mechanisms is able to provide consistent service levels, inspite of the dynamics involved in the system. It may be observed from Figure 11 that the service capacity growth in an IMSN with a feedforward system is more planned in comparison to an IMSN with just a feedback system. Since one unit of service capacity is needed to complete a single repair job

in a day, the service capacity over time in a well synchronized manufacturing service network, such as one with a feedforward system, will trace the number of incoming repairs jobs. However, due to the long lead-times in service capacity acquisition the service capacity increases only in a stepwise manner. It may also be noticed that the excess service capacity added in an IMSN with only feedback is eventually eliminated as the backlog of service jobs is cleared. The models for IMSNs with both feedback and feedforward were simulated over the entire lifecycle of the product and their profits compared. The profits in an IMSN with both feedback and feedforward mechanisms are 50% higher than the profits for an IMSN with only feedback.

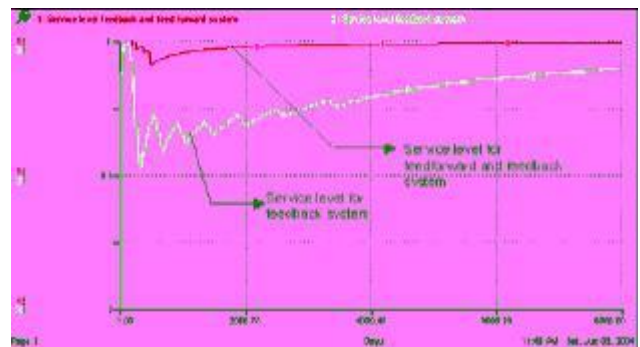

Figure 10: Comparison of service levels for an IMSN with feedback and one with both feedforward and feedback.

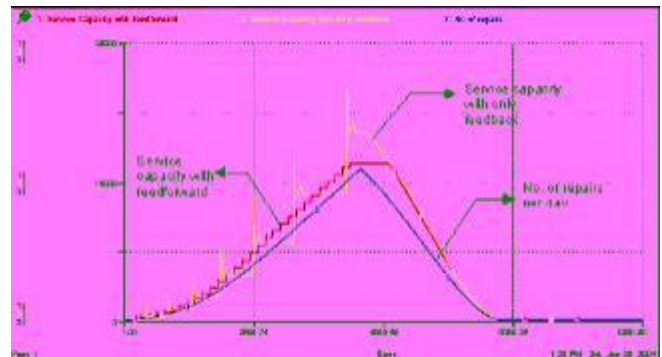

Figure 11: Comparison of service capacity for system with only feedback and system with feedback and feedforward

## 6. CONCLUSION

In this paper, we have studied the information sharing between manufacturing plant and service centres. While there are several studies in the form of business cases and white papers on benefits, ours is the first systematic study providing a framework for the analysis. In particular we study the beneficial effects of service centres feedback to design teams and sales and marketing departments. Feed forwarding the sales information to the service centres to reduce the bullwhip effect on the repair crews and spare parts.

In terms of the future, we develop multiple product

models and determine optimal time for the new product introduction. We also hope to develop queueing network and Petri net models to further study and develop analytical models.

## ABSTRACT

The operation modules and information system construction are essential contents in agile virtual enterprises. Based on the analyses of the characteristics, organization forms and operation processes in agile virtual enterprises, studies are extended to the corresponding information systems, and the development of systematic logic modules and kernel methodology is also proposed in the paper.

**Key Words:** Agile virtual enterprises, Operation modules, Management information systems

## 1. INTRODUCTION

With the development of information technology, there are great changes in global economic environments. Consumers prefer the concept of individuality and diversity, and the uncertainty of the market demand is increasing greatly. All these call for the enterprises to have flexibility and adaptability in the market. The changeable markets also call for the enterprises to have simple managerial structures, which are easy to reorganize and adjust. The customers' needs of individuality and diversity call for the enterprises to have creativity to develop new products. Consequently, the enterprises and management review the traditional managerial modes and competition models.

In 1991, supported by American National Defense Department and 13 well-known enterprises, Roger and Rick Dove, together with more than 100 experts in Iacocca Institute of Lehigh University in USA, proposed a report entitled Manufacturing Strategies of the 21st Century before the American Congress. A new manufacturing model was put forward in the report, i.e. Agile manufacturing on the basis of agile virtual enterprises (VE). The fundamental concepts of VE are that the enterprises make good use of the latest achievement in information technology and social resources and strategically join the competitive advantages of enterprises, concentrating on the development of new products and better management. The management, development, manufacturing and marketing of products are implemented by means of VE, which vary with the markets and become the kernel part of agile manufacturing.

## 2. CHARACTERISTICS OF VE

The motivation of the emergence and development of VE is to fulfill the joint destinations and to achieve the agile effects. The characteristics are integration, agility, virtuality and time-validity.

ð *Integration of VE:* Integration indicates that the relevant enterprises with varied managerial advantages dedicate their competitive privileges to the VE, conforming and exerting their unity effects in order to develop prominent competitive edge. This can be realized by means of resources conformity and resources complementation. Integration is the primary function of VE and also the major approach to the system reconstruction.

ð *Agility of VE:* Agility indicates that the enterprises are able to react and accommodate to the demands of the dynamic markets by grasping the market opportunities and promoting creativity, such as being reconfigurable, being reusable, and being scalable, namely RRS characteristics. From the perspective of business management, these characteristics refer to connection, cross-organizational participation, manufacturing flexibility and managerial relevance.

ð *Virtuality of VE:* In order to fit the dynamic markets, the structure between members is not stable, but they can reconstruct in terms of changing objectives, replacing products and varying environment, namely organizational virtuality. The VE have functions such as manufacturing, assembling, management and finance, but there are no corresponding internal organizations, namely functional virtuality.

ð *Time-validity of VE:* VE are based on the market opportunities, uniting or dismantling in terms of business opportunity. Their members are autonomous and independent.

## 3. ORGANIZATION OF VE

The managerial approaches of VE focus on the production procedures, adopting the forms of teamwork. There are four tiers, namely Virtual Enterprise (VE), Virtual Group (VG), project team based on products or services (TEAM) and Basic Organization Unit (BOU).

The first tier is the virtual enterprise made up of numerous functional projects. The second tier is the cooperation between enterprises made up of many functional projects by information network, and their methods of cooperation are virtual cooperation, interrupted compatibility, transference and supply chains. The third tier is the mobile organization between

enterprises by establishing basic organization units. The fourth tier is the basic manufacturing organization units made up of equipment, staff and technology. All the four tiers represent the many-to-many mapping between the physical material and dynamic associations within the enterprises, illustrated as Figure 1.

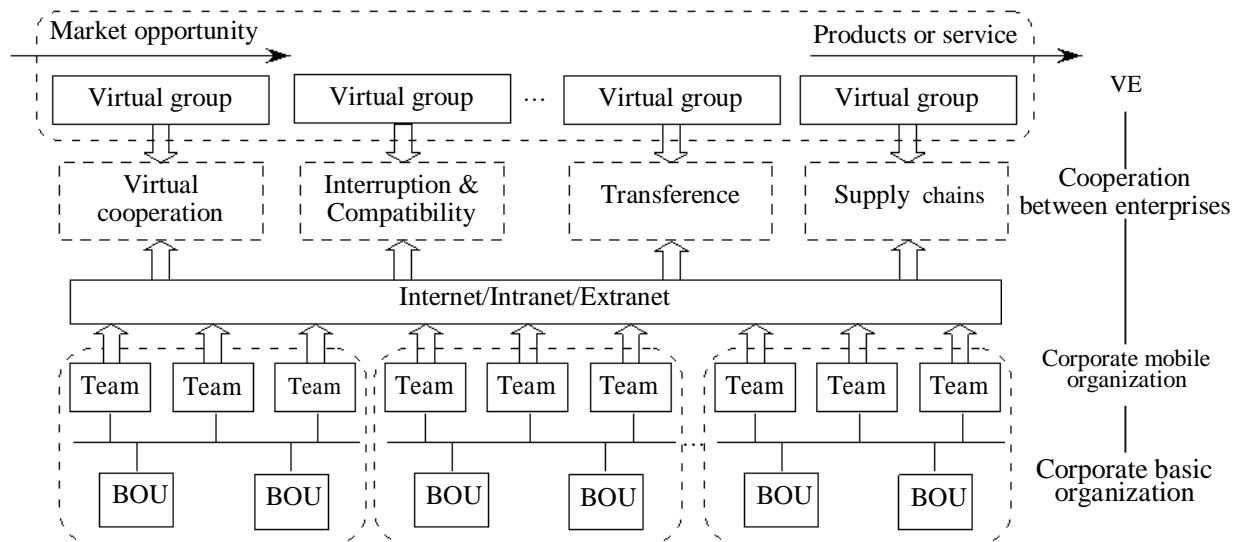

Fig.1 The Description of Tier Structures of VE

In the construction of VE, the procedure is as follows: the description of the business opportunity → definition of the business processes → the confirmation of the essential resources → selection of the business partners → decision on the cooperation strategies → the allocation of the profits and risks → management of dynamic organization. The whole procedure involves priority combination issues between internal organizations, between internal and external organizations, and between members among other cross-disciplines, etc. The ultimate goal is to establish the effective cooperation by setting up network system.

#### 4. MANAGEMENT PROCESSES IN VE

The management of VE is proposed by one or several enterprises that manipulate the essential resources (e.g. vital technology, markets or brands), and members provide their predominant resources and share the risks and profits. Consequently, the management of VE can be decomposed into 5 phases.

ð *Identification of Business Opportunity*: It is the starting point to grasp and identify the business opportunities. There are varied approaches for VE to acknowledge the business objects, namely market investigation and prediction, analyses of the market feedback, research and development of new products, analyses of market competition and social environments. The VE will discover the potential products and service in the market in

terms of the product and technology development strategies of their members.

ð *Structural Analyses of VE*: The advantages of Virtual Enterprise are gained by means of sharing information between enterprises and harmonizing the production and management processes within enterprises. The member enterprises achieve their supply of chance products or services by their own kernel capability. VE ensure the demand resources in light of the characteristics of the chance products, involving the resource distribution and the conditions of Internet communications between resource possessors. The coalescence capability plays a vital role in the success of VE.

ð *Selection of Partners and Establishment of VE*: VE make profits through time-limited cooperation and reset of kernel resources, and they also concentrate the market objectives, investigate and evaluate the relevant potential partners. In particular, the evaluation of the vital capabilities is the basis for the selection of partners. VE observe such principles as resource complementation, profit sharing and risk partaking, define the allocation forms, ensure the relationship between member enterprises and accomplish their establishment. Sound allocation programs of risks and profits are the important bases for the establishment and normal operation of VE.

ð *Managing, Tracing and Recording*: Members of VE have cooperation and competition. In terms of

regulations and market situations, VE adjust organizational structures dynamically. If the feedback suggests that there are great changes in the member enterprises and markets, VE will reorganize and even disorganize.

- ð *Reckoning and Disorganizing*: When VE complete the specific products and services of the business opportunity, they will reckon the correspondent expenditure, rights and interests in light of the contracted interest-allocating program, involving the apportionment of management expenditure, development expenditure, and manufacturing expenditure. Additionally, VE reckon the funds in the business management, and tackle with the belonging of the new technology and its future application. These processes will occur during the operation or after the disorganization of VE.

## 5. MIS OF VE

In the relatively balanced market environment, the traditional information system plays a vital part in the business management of enterprises. However, in the chaotic changeable environments, particularly in the virtual manufacturing module that is the major structural form in VE, the business information systems are required to accommodate quickly to the changes and development of enterprises. Compared with the traditional information system, the prominent characteristics of the management information system (MIS) of VE are the complete distribution of the system information, structures and functions, dynamic reorganization and agility.

### 5.1 Characteristic of MIS of VE

- ð *Openness and Compatibility*: VE is a new type of virtual business that takes the advantage of the network information technology and breaks the regional barriers. Information flows between member enterprises and within enterprises, which requires that the Management Information System within VE is not blocked and that diversified management information system can be integrated.
- ð *Flexibility*: The reconstruction of dynamic business operation and the reorganization of the units require that the corresponding MIS is rather flexible for VE so that it can execute functional integration and adjustment, and meet the needs of new business flows after the dynamic reorganization.
- ð *Robustness*: MIS in Virtual Enterprise is quite sophisticated, which meets the demand of the information integration and management between and within member enterprises. It should be reliable and effective, and it is robust in supporting large-scale cooperation on the basis of multi-disciplines and multi-tiers.

### 5.2 Logic Module of MIS in VE

In the logic module of MIS in VE, there is information flow within enterprises, between member enterprises, between enterprises and the environment, between VE and the environments, illustrated in Figure 2.

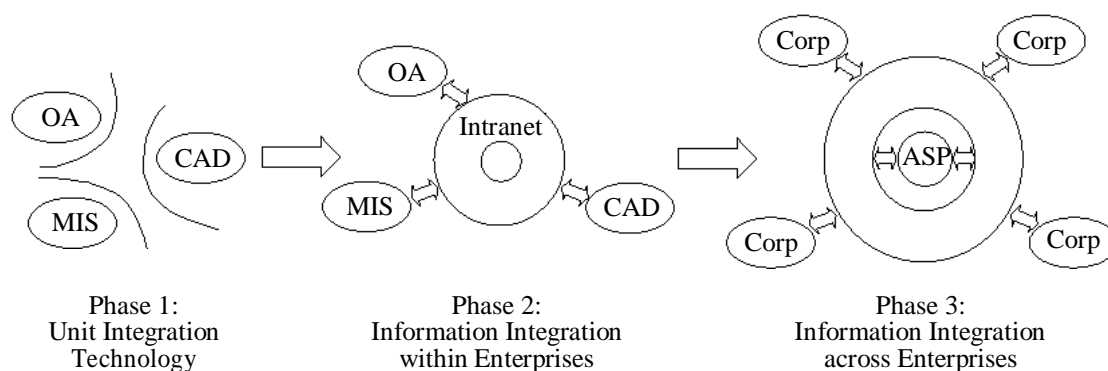

Fig.2 Logic Module of MIS in VE

Information flow within enterprises is based on Intranet. Their MIS is responsible for the collection and settlement of the basic data of enterprises, corresponding to the treatment of the businesses and interior information in all the business management departments and all the production phases. It provides the enterprises with environment for information sharing, communication, cooperation and decision-making. Object-Oriented Methodology has such characteristics as encapsulation, inheritance,

multi-states, modifiability, dynamic connection and being reusable, so that it is convenient to develop the renovative and connective MIS. The designing concept is based on the business opportunity and production missions of the enterprises. Objects are selected from the object-bank, orderly business processes and sound business organizations are matched. The parameters are configured corresponding to subsystems such as people, property, materials, production, supply, sales,

prediction and decision-making of business management.

Information flow between member enterprises is based on Extranet. Their MIS is outstretched, and it is a cooperative network that makes enterprises connect and accomplish their mutual goals. It can be a bridge between public Internet and specialized Intranet. It assumes the information communications between intimate member enterprises. It can also be viewed as a part of Intranet between the enterprise and its cooperative enterprises.

Information flow between VE and the environment is based on Internet. Their MIS is applied to information promulgation and communication, advertising systems, e-commerce systems, which can be fulfilled through setting up corresponding external server of the enterprises. Regarding the security of the system, data bank safety of MIS and network system safety are the two major factors to be considered.

### 5.3 Core Methodology of MIS in VE

This sort of information flow is integrated in enterprises on the basis of Internet/Intranet/Extranet technology, and supported by significant technology, namely object-oriented methodology (OOM), standard for the exchange of product model data (STEP), a module-setting language (EXPRESS), common object request broker architecture (CORBA).

OOM expresses through objects. It is corresponding to the characteristics of VE such as versatile information data and enormous data quantity. Also, it improves the encoding efficiency, system maintenance, and the capability to be reusable.

STEP is to offer data module in establishing distributive information system for VE, and then it is transferred to the traditional package treatment data through corresponding formats.

EXPRESS is to present objects, information units of the objects, and the operation that confines and permits the objects. It is a formal information module-setting language, and it provides the datum information that has the engineering datum structure and distributive information system conforming to STEP.

CORBA is an essential communication mechanism that can operate between distributive objects, and it is a canonical system construction that can make an individual visit to objects possible in a separate structural systems. It defines a structure for object request broker (ORB), and it meets the demand of inter-operation between management objects and applications, and the compatibility of the separate structural systems. Additionally, it can maintain the relative independence between member enterprises.

Information Treatment Methodology of agile virtual enterprises also involves:

- ò open inter-operable underlying network protocols (TCP/IP, HTTP, RMI, SOAP),
- ò open distributed object oriented middleware services (J2EE Framework, ActiveX Framework),
- ò information/object exchange mechanisms and tools (XML, ebXML, WSDL),
- ò standardized modeling of business components, processes and objects (EJBs, OAG and OMGs Business Objects and Components),
- ò business process modeling tools and languages (UML, UEMML, WfMC XML-based Business Language, PSL),
- ò open and standard business process automation and workflow management systems (WfMC, OMG-JointFlow, XML-WfMC standards, many commercial products),
- ò standard interfacing to federated multi-databases (ODBC, JDBC),
- ò intelligent mobile agents (FIPA, OMG-MASIF, Mobile Objects),
- ò open and standard distributed messaging middleware systems (JMS, MS-Message Server, MQSeries, FIPA-ACC),
- ò XML-based E-commerce protocols (BizTalk, CBL, OASIS, ICE, RosettaNET, OBI, WIDL),
- ò web integration technologies (Servlets, JSP, MSASP, XSL).

The current security mechanisms can be fulfilled through safety methodologies such as the state and behavior of datum bank, rich semantic association, the specification of managerial purview, datum encryption methodology, firewall technique, network security scanning methodology, network invasion testing methodology and hacker inducement methodology.

## 6. CONCLUSION

The traditional management theory concentrates on the internal relationship in the enterprises, whereas VE focus on reshaping the relationship between enterprises. The managerial methodology of VE replaces sequential management with juxtaposition managerial procedures, and replaces manipulating management with concentrated and cooperative managerial methodology. VE are the advanced organizational management behavior and market competitive strategies directed by the concept of agility, accommodating to competition and manufacturing development. The soul and kernel of VE are agility and integration.

The development and application of the Internet technology make it possible for the former enterprises to transfer the specialized information from the comparatively higher tiers to the lower tiers, and to feed back the information from the mid or lower tiers of the enterprises to the high-tier management through excavating data. Virtual enterprise modules enable

enterprises to reconstruct their production, supply, sales and service flow. All these demand that enterprises completely construct their MIS to support business management of VE. Enterprises are also required to build up concepts of competition and competition, and to integrate the external advantages through taking the advantage of internal resources, and to react quickly to the market demands, and thus to enhance the competitive edge of the kernel enterprises.

## ABSTRACT

The supplier and buyers, with different objectives and self-interest, are separate economic entities acting independently and opportunistically to maximize their individual profits. In this paper, a GBA model in the B2B market is studied, where one supplier faces 2 different retailers, who cooperate in the order decision making. Firstly, the optimal ordering decision of the retailers was analyzed. Then, from the perspective of the supplier, the optimal pricing strategy of the supplier is also studied. Finally, it is concluded that the group buying online auction is a useful and efficient pricing mechanism in the B2B e-market, under which, all members of the supply chain will improve their payoffs.

**Keywords:** Group-buying online auction, supply chain, newsvendor model, B2B market

## 1. INTRODUCTION

The supplier and buyers, with different objectives and self-interest, are separate economic entities acting independently and opportunistically to maximize (minimize) their individual profits (costs). An effective supply chain network requires a cooperative relationship between the vendor and the buyer. Based on mutual trust, the cooperation includes the sharing of information, resources and profit. One of the most common strategies is to setup a pricing policy acceptable to both the vendor and the buyer. (Yang, 2004).

The price discount policy is a subject of significant interest. Starting from Crowther (1964), Monahan (1984) was one of the early authors who analyzed a vendor-oriented optimal quantity discount policy that maximized the vendor's gain; it is done at no additional cost to the buyer. Lee and Rosenblatt (1985) generalized Monahan's model and developed an algorithm to solve the vendor's ordering and discount-pricing policy. Buscher and Lindner (2004) further extend Lee and Rosenblatt's model.

However, their objective function is restricted to maximizing the supplier's profits only. Zahir and Sarker (1991) consider a price-dependent demand function for multiple regional wholesalers who are served by a single manufacturer. Meantime, in recent years, some studies have paid the attention on the perishable product with the policy of price discount. Wee (1999) introduces a deterministic inventory model with quantity discount, pricing and partial backordering when the product in stock deteriorates with time. Papachristos and Skouri (2003) generalize the work of Wee and consider a model where the demand rate is a convex decreasing function of the selling price and the backlogging rate is a time-dependent function, which ensures that the rate of backlogged demand increases as the waiting time to the

following replenishment point decreases.

In our paper, we also analyze the two-echelon supply chain consisting of one vendor and multiple different buyers, in which, the products is perishable. The main difference between our work and theirs is that a particular pricing mechanism, the Group buying online auction, is employed in our study.

Group-buying auction is also a kind of quantity discount form. However, the GBA, unlike the traditional discount, does not lead to price discrimination among different buyers and every buyer will be charged the same price. Each buyer in the GBA will only buy a piece of product which means the price declines monotonically in total purchase quantities of all buyers, and not just an individual buyer's purchase quantities. These are much different from the traditional quantity discount policy.

Moreover, the group-buying auction (GBA), a homogeneous multi-unit auction, has many users on sites such as LetsBuyIt.com and Yabuy.com. Different from traditional auctions, where bidders compete against one another to be the "winner" with the highest price, the GBA enables bidders to aggregate to offer a lower price at which they all "win" (Horn et al. 2000). When using the GBA as the pricing mechanism, it is helpful to refer to traditional auction models. By considering the seller's expected revenue, Vickrey (1961) proves the well-known Revenue Equivalent Principle and Myerson (1979) proves the Revelation Principle. The details about traditional auction studies can be found in Klemperer's (1999) survey. However, the traditional auction theory does not consider inventory because it is not an important issue for those products. Internet expands online auction markets, where almost all products can be auctioned. Hence, our study tries to bridge the inventory management and auction process.

Although the GBA is widely used in the E-market, it lacks a theoretical framework and the study on the GBA is rare. Chen et al. (2002) build a dynamic game model for the GBA, based on which they study the bidders' optimal strategy. They prove that the mechanism is incentive compatible for bidders under the IPV (independent private values) assumption. Kauffman and Wang (2002a) conduct an experimental study of the GBA. They analyze the changes in the number of bids for Mobshop-listed products over various periods. Based on the empirical study of twelve GBA websites, Kauffman and Wang (2002b) point out that because the GBA is still a new concept, the websites must educate consumers to achieve a critical mass. Anand and Aron (2003) devise an analytical model to study the GBA. They compare the posted pricing mechanism with the GBA in different scenarios, e.g., demand uncertainty and scale economies of production. On the other hand, the inventory literature has paid little notice to the marketing trends (Arcelus et al., 2003). Chen et al. (2004b) consider a GBA model for a monopolistic manufacturer selling novel products in the uncertain market and link this new pricing mechanism to the newsboy model.

They, however, all do not study the GBA mechanism in the B2B market, which is a more prosper and profitable segment. Kauffman and Wang (2002b) suggest that the GBA websites oriented toward the B2B market should be better positioned for future growth. In the business practice, Mobshop changed its strategic direction from the B2C to the B2B market (Clark 2001) which is more profitable. According to Anand and Aron (2003), in the B2B market, the GBA has been employed to sell diverse goods and services, such as, furniture, commercial print, computer hardware, software, telecommunications & connectivity, electricity and gas, computer equipment, office supplies and vehicles, vegetables and company travel. To the best of our knowledge, our paper is the first in academia to study the GBA in the B2B e-market. Our effort is to regard the GBA as a useful and resultful coordination strategy in a two echelon supply chain in order to make a more effective and efficient decision in the B2B e-Market environment.

The rest of this paper is organized as follows. In section 2, we build the model with one supplier and 2 retailers. Section 3 deduces the optimal order strategy for the retailers. In Section 4, we study the supplier's optimal discount strategy. In section 5, we summarize the paper and describe the future research directions.

## 2. MODEL DESCRIPTION

Suppose two retailers, which will cooperate during the ordering decision process, order products from the same supplier and each retailer faces independent markets. First, the supplier will set the price curve  $(p_1, p_2, l)$ , where  $p_1 > p_2$ . Then the retailers will bid their order

quantity. If the sum of the order quantity is equal to or greater than  $l$ , then all the retailers pay unit price  $p_2$  to get their order. Otherwise, the unit price is  $p_1$ . Suppose retailer  $i$  faces the  $i$ th markets with unit sale price  $S_i$ , and the demand is a random variable with PDF  $F_i(\cdot)$ . At the end of the auction, the unsold products are perished with salvage 0. All information is common knowledge and the retailers make their decision simultaneously. i.e., they face a statistic game.

## 3. THE ORDER STRATEGY FOR THE RETAILERS

When no quantity discount is offered, the supplier's unit selling price is  $p$ . Then each retailer faces the situation as the newsboy model and the payoff for retailer  $i$  is

$$\int_0^{n_i} S_i x dF_i(x) + \int_{n_i}^{+\infty} S_i n_i dF_i(x) - n_i p. \quad \text{The optimal order}$$

quantity is  $n_i^* = F_i^{-1}\left(\frac{S_i - p}{S_i}\right)$  and the payoff is

$$\int_0^{n_i^*} S_i x dF_i(x). \quad \text{When using the GBA, the wholesale price}$$

is related to the sum of the retailers' order quantity, i.e., the wholesale price

$$p = H(n_1 + n_2 - l)p_2 + (1 - H(n_1 + n_2 - l))p_1,$$

$$\text{where } H(x) = \begin{cases} 1, & \text{if } x \geq 0 \\ 0, & \text{if } x < 0 \end{cases}.$$

Hence the payoff for retailer  $i$  is

$$\int_0^{n_i} S_i x dF_i(x) + \int_{n_i}^{+\infty} S_i n_i dF_i(x) - n_i (H(n_1 + n_2 - l)p_2 + (1 - H(n_1 + n_2 - l))p_1)$$

When the two retailers cooperate, their optimal strategy is to maximize the whole profit of both retailers, i.e.,

$$\begin{aligned} \max_{n_1, n_2} & \left( \int_0^{n_1} S_1 x dF_1(x) + \int_{n_1}^{+\infty} S_1 n_1 dF_1(x) + \int_0^{n_2} S_2 x dF_2(x) \right. \\ & \left. + \int_{n_2}^{+\infty} S_2 n_2 dF_2(x) \right) - (n_1 + n_2) (H(n_1 + n_2 - l)p_2 \\ & + (1 - H(n_1 + n_2 - l))p_1) \end{aligned}$$

This problem can be solved in two steps:

**[Step I]**

Solve two nonlinear programming problems

**Programming I**

$$\begin{aligned} \max_{n_1, n_2} & \left( \int_0^{n_1} S_1 x dF_1(x) + \int_{n_1}^{+\infty} S_1 n_1 dF_1(x) + \int_0^{n_2} S_2 x dF_2(x) \right. \\ & \left. + \int_{n_2}^{+\infty} S_2 n_2 dF_2(x) \right) - (n_1 + n_2)p_2 \end{aligned} \quad (1)$$

$$\text{s.t. } \begin{cases} n_1 + n_2 \geq l \\ n_1 \geq 0 \\ n_2 \geq 0 \end{cases}$$

**Programming II**

$$\begin{aligned} \max_{n_1, n_2} & \int_0^{n_1} S_1 x dF_1(x) + \int_{n_1}^{+\infty} S_1 n_1 dF_1(x) + \int_0^{n_2} S_2 x dF_2(x) \\ & + \int_{n_2}^{+\infty} S_2 n_2 dF_2(x) - (n_1 + n_2) p_1 \\ \text{S.T.} & \begin{cases} n_1 + n_2 < l \\ n_1 \geq 0 \\ n_2 \geq 0 \end{cases} \end{aligned} \quad (2)$$

**[Step II]**

Comparing the value of the objective function (1) and (2), the larger one is the optimal solution.

Using this method and based on the following theorems, we can get the retailers' optimal order strategy.

**Theorem 1** If  $n_1^* + n_2^* \geq l$ , the optimal order quantity for retailer 1 is  $N_1^* = n_1^*$ ; and that for retailer 2 is  $N_2^* = n_2^*$ .

**Proof:** Because

$$\begin{aligned} & \left( \int_0^{n_1} S_1 x dF_1(x) + \int_{n_1}^{+\infty} S_1 n_1 dF_1(x) + \int_0^{n_2} S_2 x dF_2(x) \right. \\ & \left. + \int_{n_2}^{+\infty} S_2 n_2 dF_2(x) - (n_1 + n_2)(H(n_1 + n_2 - l) p_2) \right. \\ & \left. + (H(n_1 + n_2 - l) p_1) \right) \\ & \leq \left( \int_0^{n_1} S_1 x dF_1(x) + \int_{n_1}^{+\infty} S_1 n_1 dF_1(x) + \int_0^{n_2} S_2 x dF_2(x) \right. \\ & \left. + \int_{n_2}^{+\infty} S_2 n_2 dF_2(x) - (n_1 + n_2) p_2 \right) \end{aligned}$$

we can get that

$$\begin{aligned} \max_{n_1, n_2} & \left( \int_0^{n_1} S_1 x dF_1(x) + \int_{n_1}^{+\infty} S_1 n_1 dF_1(x) + \int_0^{n_2} S_2 x dF_2(x) \right. \\ & \left. + \int_{n_2}^{+\infty} S_2 n_2 dF_2(x) - (n_1 + n_2)(H(n_1 + n_2 - l) p_2) \right. \\ & \left. + (H(n_1 + n_2 - l) p_1) \right) \\ & \leq \max_{n_1, n_2} \left( \int_0^{n_1} S_1 x dF_1(x) + \int_{n_1}^{+\infty} S_1 n_1 dF_1(x) + \int_0^{n_2} S_2 x dF_2(x) \right. \\ & \left. + \int_{n_2}^{+\infty} S_2 n_2 dF_2(x) - (n_1 + n_2) p_2 \right) \\ & = \int_0^{n_1^*} S_1 x dF_1(x) + \int_{n_1^*}^{+\infty} S_1 n_1^* dF_1(x) + \int_0^{n_2^*} S_2 x dF_2(x) \\ & \quad + \int_{n_2^*}^{+\infty} S_2 n_2^* dF_2(x) - (n_1^* + n_2^*) p_2 \end{aligned}$$

since  $n_1^* + n_2^* \geq l$ , hence

$$\begin{aligned} & \int_0^{n_1^*} S_1 x dF_1(x) + \int_{n_1^*}^{+\infty} S_1 n_1^* dF_1(x) + \int_0^{n_2^*} S_2 x dF_2(x) \\ & \quad + \int_{n_2^*}^{+\infty} S_2 n_2^* dF_2(x) - (n_1^* + n_2^*) p_2 \\ & = \int_0^{n_1^*} S_1 x dF_1(x) + \int_{n_1^*}^{+\infty} S_1 n_1^* dF_1(x) + \int_0^{n_2^*} S_2 x dF_2(x) \\ & \quad + \int_{n_2^*}^{+\infty} S_2 n_2^* dF_2(x) - (n_1^* + n_2^*)(H(n_1^* + n_2^* - l) p_2) \\ & \quad + (H(n_1^* + n_2^* - l) p_1) \end{aligned}$$

Therefore, it can be deduced that  $(n_1^*, n_2^*)$

$$\begin{aligned} & = \arg \max_{n_1, n_2} \left( \int_0^{n_1} S_1 x dF_1(x) + \int_{n_1}^{+\infty} S_1 n_1 dF_1(x) + \int_0^{n_2} S_2 x dF_2(x) \right. \\ & \quad + \int_{n_2}^{+\infty} S_2 n_2 dF_2(x) - (n_1 + n_2)(H(n_1 + n_2 - l) p_2) \\ & \quad \left. + (H(n_1 + n_2 - l) p_1) \right) \end{aligned}$$

**Q.E.D**

**Lemma 1** The equation group

$$\begin{cases} n_1 + n_2 = l \\ S_1(1 - F_1(n_1)) = S_2(1 - F_2(n_2)) \end{cases}$$

has one and only one solution  $(z_1, z_2)$ .

**Proof:** The existence of the solution is clear. Now, we will prove the uniqueness of the solution. Suppose there are two pairs of solutions  $(z_1, z_2)$ ,  $(z_1', z_2')$ . Because  $z_1 + z_2 = z_1' + z_2' = l$ ,  $z_1 - z_1' = z_2' - z_2$ , hence  $(F_1(z_1) - F_1(z_1'))(F_2(z_2) - F_2(z_2')) < 0$ .

Since

$$\begin{aligned} S_1(1 - F_1(z_1)) &= S_2(1 - F_2(z_2)), \\ S_1(1 - F_1(z_1')) &= S_2(1 - F_2(z_2')), \end{aligned}$$

We can deduce that

$$S_1(F_1(z_1) - F_1(z_1')) = S_2(F_2(z_2) - F_2(z_2'))$$

which contrasts to

$$(F_1(z_1) - F_1(z_1'))(F_2(z_2) - F_2(z_2')) < 0 \quad \text{Q.E.D.}$$

Suppose

$$\begin{aligned} \pi_1 &= \left( \int_0^{z_1} S_1 x dF_1(x) + \int_{z_1}^{+\infty} S_1 z_1 dF_1(x) + \int_0^{z_2} S_2 x dF_2(x) \right. \\ & \quad \left. + \int_{z_2}^{+\infty} S_2 z_2 dF_2(x) - l p_2 \right) \\ \pi_2 &= \left( \int_0^{n_1^*} S_1 x dF_1(x) + \int_{n_1^*}^{+\infty} S_1 n_1^* dF_1(x) + \int_0^{n_2^*} S_2 x dF_2(x) \right. \\ & \quad \left. + \int_{n_2^*}^{+\infty} S_2 n_2^* dF_2(x) - (n_1^* + n_2^*) p_1 \right) \end{aligned}$$

**Theorem 2** If  $n_1^* + n_2^* < l$  and  $\pi_1 > \pi_2$ , the optimal order quantity for two retailers is  $N_1^* = z_1$ ;  $N_2^* = z_2$  respectively. Otherwise, the optimal solution is

$$N_1^* = n_1^*; N_2^* = n_2^*$$

**Proof:** If  $n_1^* + n_2^* < l$ . Using K-T condition, the optimal solution for Programming I is  $(z_1, z_2)$  and the objective value is  $\pi_1$ . The optimal solution for Programming II is  $(n_1^*, n_2^*)$  and the objective value is  $\pi_2$ . Therefore, we can deduce the result directly.

**Q.E.D**

Based on the above theorems, the optimal order quantity for retailer  $i$ ,  $N_i^*$ , can be calculated with the following algorithm.

**[Step I]**

Comparing  $n_1^* + n_2^*$  with  $l$ , if  $n_1^* + n_2^* \geq l$ , the optimal retailer 1 is  $N_1^* = n_1^*$ ; and that for retailer 2 is  $N_2^* = n_2^*$ . Otherwise, we will begin the step II.

**[Step II.]**

Comparing  $\pi_1$  with  $\pi_2$ . If  $n_1^* + n_2^* < l$  and  $\pi_1 > \pi_2$ , the optimal solution is  $N_1^* = z_1$ ;  $N_2^* = z_2$ . Otherwise, the optimal solution is  $N_1^* = n_1^*$ ;  $N_2^* = n_2^*$ .

#### 4. THE SUPPLIER'S OPTIMAL DISCOUNT STRATEGY

We use a Stackelberg game framework to study the supplier's strategy. When no quantity discount is offered, the supplier's unit selling price is  $p$ . Then the supplier's profit is  $(p - c)(n_1^* + n_2^*)$ . When using GBA, with price curve  $Q$ , suppose the retailer  $i$ 's optimal order quantity according the former section is  $N_i(Q)$ , the payoff of the supplier is

$$(H(N_1(Q) + N_2(Q) - l)p_2 + (1 - H(N_1(Q) + N_2(Q) - l))(p_1 - c)(N_1(Q) + N_2(Q)))$$

The supplier will determine the discount price  $p_2$  and discount quantity threshold  $l$ .

**Assumption 1** Suppose if order  $N_1$  and  $N_2$  will bring the retailer the same expected profit and  $N_1 < N_2$ , the retailer will choose  $N_2$  because more order quantity implies a higher consumer satisfaction.

The supplier will determine the discount price  $p_2$  and discount quantity threshold  $l$ .

Let we define

$$\pi = \int_0^{n_1^*} S_1 x dF_1(x) + \int_0^{n_2^*} S_2 x dF_2(x),$$

$$n_1(l) \text{ and } n_2(l) \text{ s.t. } \begin{cases} n_1(l) + n_2(l) = l \\ S_1(1 - F_1(n_1(l))) = S_2(1 - F_2(n_2(l))) \end{cases},$$

for any given  $p_2$ , suppose the discount threshold is  $l(p_2)$  s.t.  $l(p_2) > n_1^* + n_2^*$  and

$$\pi = \left( \int_0^{n_1(l)} S_1 x dF_1(x) + \int_{n_1(l)}^{+\infty} S_1 n_1(l) dF_1(x) + \int_0^{n_2(l)} S_2 x dF_2(x) + \int_{n_2(l)}^{+\infty} S_2 n_2(l) dF_2(x) \right) - l(p_2)p_2$$

**Lemma 2** For any given  $p_2$ , optimal  $l(p_2) \geq l(p_2)$

**Proof:** If  $l < l(p_2)$

Case 1: if  $l \leq n_1^* + n_2^*$ , the sold quantity is  $n_1^* + n_2^*$  and the price is  $p_2$ . The supplier's profit is  $(n_1^* p_2 + n_2^* p_2)(p_2 - c) < l^*(p_2)(p_2 - c)$ .

Case 2: if  $n_1^* + n_2^* < l < l(p_2)$ , the sold quantity is  $l$ , and the supplier's profit is  $l(p_2 - c) < l^*(p_2)(p_2 - c)$ .

Hence set  $l < l(p_2)$  is not optimal for the supplier.

**Q.E.D**

If  $l > l(p_2)$ , the retailer  $i$ 's order quantity is  $n_i^*$  and the supplier's profit is  $(p_1 - c)(n_1^* + n_2^*)$ . When  $l = l(p_2)$ , the supplier's profit is  $(p_2 - c)l = (p_2 - c)l(p_2)$ . Let  $p_2^* = \arg \max_{p_2} (p_2 - c)l(p_2)$ . Then the supplier's optimal profit is  $(p_2^* - c)l(p_2^*)$ .

**Theorem 3** If  $l = l(p_2)$  and  $(p_2^* - c)l(p_2^*) > n_1^* + n_2^*$ , the optimal price curve is  $(p, p_2^*; l)$ ; else, trading price will keep  $p$ , i.e. the supplier should not use GBA, i.e., do not offer any discount.

Employing the GBA, all the supplier and retailers will get more profit, i.e., it is a Pareto improvement.

#### 5. CONCLUSIONS AND FUTURE RESEARCH

In this paper, we employ the group-buying auction as a special pricing mechanism and study the supplier and retailers' discount strategy and order strategy in the B2B e-Market. After building up the model framework, we optimize the retailers' payoff and deduce the optimal order strategy. Then, from the perspective of the supplier, the optimal discount strategy is also studied. We conclude that with the GBA, all members of a supply chain will improve their profits.

In our model we assume that the retailers are cooperative with each other during the ordering decision. However, if they make the decision completely independently, it is another story. Hence, it is interesting and meaningful to study such a case.

Another important area for the future research is to extend the number of the retailers from 2 to  $k$ . It is more practical and helpful for the decision making of the supplier.

## ABSTRACT

Collaborative Commerce (C-Commerce) is the name given to commercial relationships carried out over a collaborative framework to integrate enterprises' business processes, share customer relationships and manage knowledge across enterprise boundaries. This is a business strategy that leverages the extensive reach of the Internet. C-Commerce places emphasis on supply chain involvement where members of the supply chain work together to design, build, market and deploy products and services. Collaborative commerce is the next generation of E-commerce framework. E-logistics is the mechanism of automating the logistics processes and providing an integrated, end-to-end fulfillment and supply chain management service to the players of logistics processes. This paper attempts to design an integrated framework for an E-logistics model that it can be effectively employed for C-Commerce.

**Keywords:** Collaborative Commerce, E-Logistics

## 1. INTRODUCTION

Collaborative Commerce (C-Commerce) is the name given to commercial relationships carried out over a collaborative framework to integrate enterprises' business processes, share customer relationships and manage knowledge across enterprise boundaries. The ultimate aims of C-Commerce initiatives are to maximize return on intellectual capital investment, business agility and the quality of the customer experience. C-Commerce is a business strategy that leverages the extensive reach of the Internet. C-Commerce places emphasis on supply chain involvement where members of the supply chain work together to design, build, market and deploy products and services. This helps to accelerate the business pace, creates barriers to entry in a particular industry, it enhances customer loyalty, and enables new business models. It is far more crucial than basic B2B e-commerce that is designed to construct a virtual link for a pre-defined community of trading partners to buy or sell goods and services. Even after the fall of the dot.com era, corporate strategies and venture capitalists are embracing C-Commerce as the next generation of e-commerce and an evolution of the traditional supply chain process [1].

There are major driving forces that led to the development of c-commerce. They include expansion of global communications, cost efficiency and economies of scales, customer anticipations of cheaper and better products along with faster delivery and fast access to information, high-speed communication networks. Additionally, some of the driving forces incorporate high-speed communication networks, affordability of business applications, quick deployment, and standardization of technology [2].

The three ingredients for effective C-Commerce are (a)

Managing supply chain, (b) Leveraging technology, and (c) Adapting business models to current market environment. There are six critical factors identified for any organization to successfully evolve from E-commerce to C-Commerce [4]. These factors are:

1. Desire and capacity for fundamental change
2. Internal capabilities for collaboration
3. Tolerance for managed risk
4. Organizational agility
5. Effective implementation
6. Disciplined approach to performance measurement

Today, collaboration is the key factor enabling companies to transcend traditional constraints and perform competitively in a dynamic, increasingly complex business environment [3].

## 2. NEXT GENERATION E-COMMERCE

Collaborative commerce is the next generation of E-commerce framework. E-commerce is different in the sense that it primarily deals with transaction involving order placement, fulfillment, and payment delivery whereas C-commerce provides dynamic, web-enabled exchange of intellectual capital within enterprise and trading partners to optimize product development, supply chain operations, and manufacturing processes [5].

The Figure-1 above represents how C-Commerce brings people together to make real time decisions across organizational boundaries. It also unites the enterprise in a single secure environment.

### 2.1 Stages of C-Commerce Evolution

With the birth of the Internet, companies started to do commerce on line with storefront models, from there,

companies started to use the Internet to help make their internal processes better so that they can provide better products and customer service and increase profits by lowering transaction cost using Internet technologies like EDI. The next evolution was the use of the Internet by companies to connect to their suppliers. This allowed for lower inventory cost, better customer service - getting the product there at the right time, and increase in efficiency and productivity from both ends [6].

## 2.2 Enablement of Multi-Dimensional Collaboration

Web services allow organizations to participate in multi-dimensional collaboration where organizations can collaborate with several partners at a time. This increases inter-enterprise processes and supply-chain velocity. C-commerce is vital in streamlining business process and bringing cost efficiencies and revenue potential for today's organizations, and with the use of Web services integration among business processes is faster and better [7].

## 2.3 How Web Services Redefine C-Commerce?

So far, we are in a very early stage in the evolution of web business. We have been able to overcome the issue of the standardization of enterprise application programming interfaces around the web, and have managed to undertake tremendous business-to-business exchange transactions over the web, albeit with high integration costs. Web Services promise to revolutionize this process.

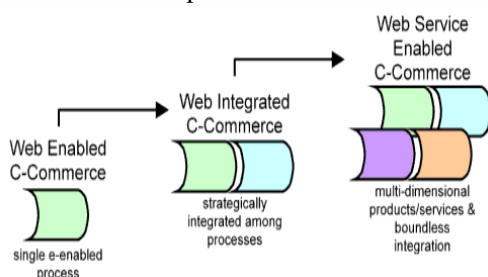

Figure 2

In the figure above, we can see the three stages of c-commerce, from bottom-left to top-right:

**First stage of C-Commerce** - web enabled c-commerce, a one dimensional, single e-enabled business process that allows certain internal data to be visible to external trading partners, and vice versa. Typically, this meant implementing a web presentation of the data, and allowing partners access to it. This is a limited form of c-commerce, with very limited value, saving only labor cost. Typical applications would be displaying demand for production materials, showing sales forecasts to suppliers, or presenting bills electronically.

**Second stage of C-Commerce** - B2B exchanges in markets such as steel, auto parts, chemicals or airline equipment. Buyers, sellers and suppliers are integrated

through a web portal. In this stage, each enterprise can reconfigure its supply chain through the marketplace to leverage aggregated buying power and eliminate brokerage fees and middlemen.

The first two stages of C-Commerce have never reached the critical mass required for mass adoption by all industries, because of the cost of integration.

**Third stage of C-Commerce** - will be built on Web Service as a core integration engine to deliver seamless process integration, seamless customer satisfaction integration and seamless product design integration. It is a plug and play sort of C-Commerce rather than a hard-wired, integration driven effort. A new study by strategy consultants Roland Berger provides an in depth look and guide for the current development of business-to-business (B2B) E-Commerce in the consumer goods industry. Last year both manufacturers and retailers began to invest heavily in B2B initiatives such as the GlobalNetXchange and Transora. For leading industry CEOs and senior executives the key question is how will Internet exchanges affect relationships with their retail customers. Customer relationship management and supply chain processes are, for many consumer goods companies, major sources of differentiation and competitive advantage [8].

## 3. LATEST GENERATION OF SUPPLY CHAIN MANAGEMENT

The latest generation of supply chain management is Web-Centric. It is characterized by the marriage of the Internet and the supply chain and has resulted in the birth of electronic business (e-business) applications. These Internet enabled, e-business applications have Internet integrated all branches of the supply chain and emerged as the most cost effective means of supply chain operation [9]. E-business applications (e-procurement, e-commerce, and e-collaboration applications) change the supply chain from a linear, rigid chain into a dynamic chain based on an information hub called an ERP (Enterprise Resource Planner), as shown in Figure 3 below.

### The Spoke and Wheel Internet-Enabled Supply Chain

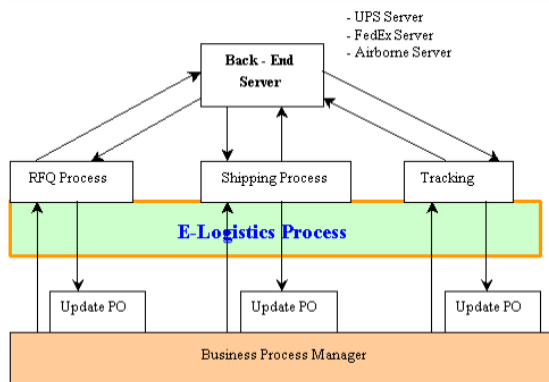

Figure 3

When it comes to logistics, the challenge has always been how to deliver products to customers as quickly and safely as possible. Logistics is concerned with the flow of materials in the supply chain, from source through the industrial process to the customer, and then on to re-use, re-cycle, or disposal. By coordinating all resources, logistics have to ensure that service level agreements with customers are honored. Efficient logistics can result in cost savings, which can be passed on to the customer, often resulting in increased business [10].

#### 4. E-LOGISTICS

E-logistics is the mechanism of automating the logistics processes and providing an integrated, end-to-end fulfillment and supply chain management service to the players of logistics processes. Those logistics processes that are automated by e-logistics provide supply chain visibility and can be part of existing e-commerce or workflow systems in an enterprise [13] [14] [16] [18].

The typical e-logistics processes include Request For Quotes (RFQ), Shipping, and Tracking. As shown in the following diagram, e-Logistics interacts with the business process manager in an e-commerce server such as B2B (business to business) or B2C (business to consumer) server, as shown in the Figure 4..

**Figure 4**

The business process manager invokes the RFQ process to get the basic services such as obtaining the quotes in an e-logistics process. Whenever a response is obtained, the purchase order (PO) will be updated. The shipping process is also invoked by the business process manager and will update the corresponding PO upon

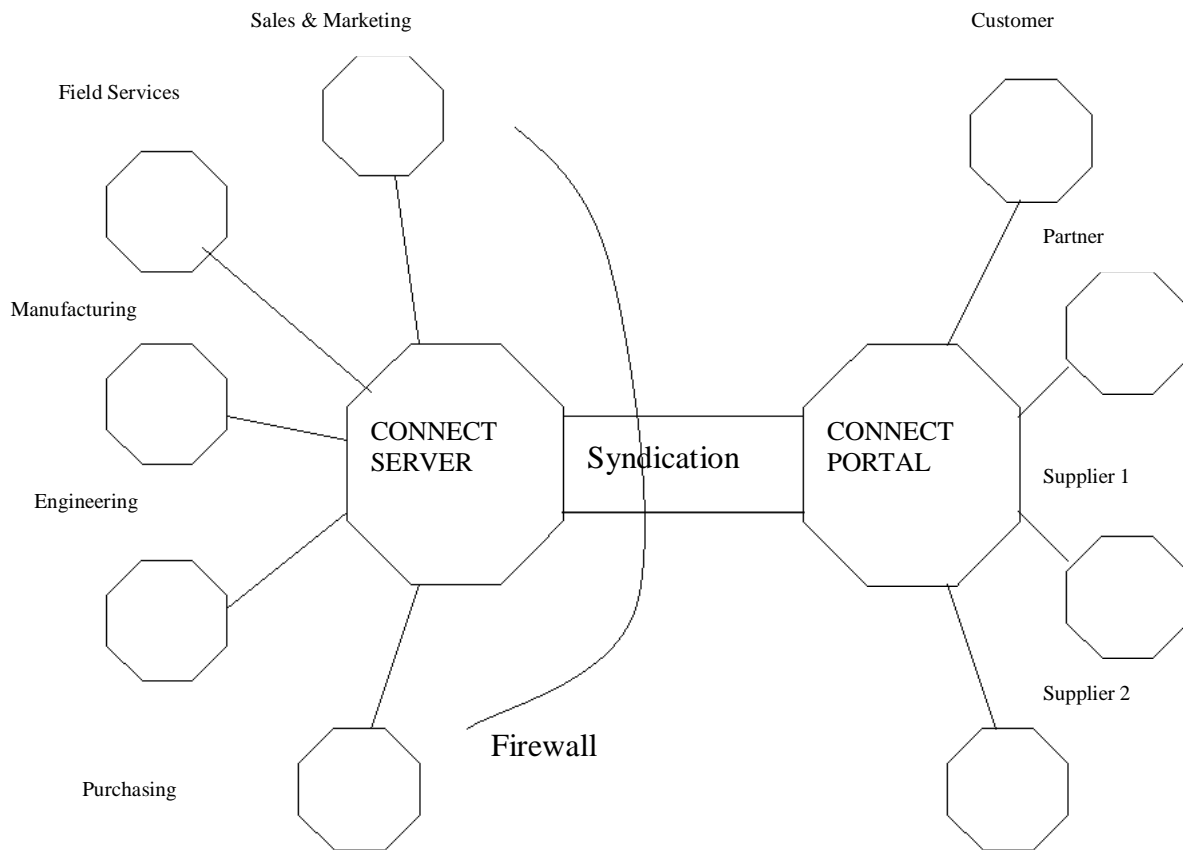

completion. Along with the shipment of goods, a tracking number will be given to the customer and that tracking number will be bound to the PO number in the processing e-commerce system. Customers can track their shipment with the help of that number. The interaction diagram of e-logistics and business process manager shown above represents the high-level view of ELPIF.

#### 5. CONCLUSION

Because the Internet extends around the world, it offers the perfect information sharing channel for logistics. With it, customers can buy and pay for materials, direct their delivery, and trace an order every step of the way. Organizations realize that a strong supporting logistics or electronic logistics (e-logistics) function is an important organizational offering from both the commercial and consumer perspective. The implications of e-logistics models and practices cover the forward and reverse logistics functions of organizations. They also have direct and profound impact from an environmental perspective. This paper tries to come out with a framework to implement C-commerce with the active help of E-logistics.

## ABSTRACT

Internet services in distributive organization are normally built on an open network environment. In the environment internet service provisioning cannot be expected executing in a single close organization [1]. Identity management in cross-organization becomes an issue for handling Internet service and distributive business process.

The “identity” in cross-organization web service is defined as global identity rather than private identity from client. Global identity searching table that registers all related service organization is the normal way we used to [2]. Through global identity searching table the target service organization can be looked up directly. For some business program, however, global identity is not necessary registered in specific service organization, e.g. IMSI (International Mobile Subscriber Identification) registration in NP (Number Portability) Service [3], for instance. In NP Service each IMSI can be re-assigned to different mobile service provider if the IMSI apply the re-assignment.

In the example about IMSI in NP service mentioned above, if there is an internet service will be executed according to identity management with IMSI, then it will be a challenge to find the organization for available IMSI in very short response time. To dynamically re-assign a IMSI in different mobile service provider, the traditional global identity searching table will not be practical due to frequently changing the registration of IMSI in different service provider.

To give an intelligent searching model for cross-organization global identity management is a better way than a static global identity searching table management in Web service. In this article the XCS (eXtended Classifier System) classifier system [4] will be proposed as the kernel system. With the characteristics in machine learning and rules management, the XCS-based intelligent searching model can help to predict where the web service can find the global identity in the open and cross-organization environment.

**Keywords:** Identity Management, Cross-Organization Searching Model, Web Service, XCS Classifier System

## 1. INTRODUCTION

The cross-organization web service allows a user to seamlessly traverse different sites on different organizations [1]. For any cross-organization service in Internet, global identity is not necessary found from first organization which detects service request from client. It implies that service organization should be “searched” if it will offers required global identity.

In this field a lot of searching scheme under the assumption of fixed network topology, such as Microsoft TrustBridge [6], IBM Tivoli Federated Identity Authentication System and Secure Web Service [7], etc.. Most of major applications for m-commerce or e-commerce, identity management is developed as same way in opening internet environment [1][9].

For any changing in an opening cross-organization web environment, re-configuring of network topology, routing table will be overhead of adjusting global identity distribution. Therefore, the design of an intelligent searching model for getting right service

organization is the major topic in the article.

For achieving the objective, an XCS-Based intelligent searching model for accessing cross-organization global identity is proposed. Not only give the capability to find required global identity in dynamic service organization, but also give capability in searching rules management, learning and GA based evolutionary operations.

## 2. IDENTITY MANAGEMENT IN CROSS-ORGANIZATION WEB SERVICE

Identity management in cross-organization web service is more complicated than in single organization environment. The major problems are:

1. The table schema for depicting global identity in cross-organization is complicated.
2. The prediction for global identity in unknown organization is not easy to perform.

Before answering the issues mentioned above, some fundamental research should be performed in advanced.

## 2.1 Cross-Organization Web Service

Web service is the major communication mechanism in e-commerce. Through web service, flexibility to business partners, suppliers and customers is the major inspiration for business operation. Some standards in web service were taken. These standards normally solve the problems of finding, binding and accessing service. The major standards in web service include UDDI (Universal Description, Discovery and Integration), WSDL (Web Service Definition Language) [8], SOAP (Simple Object Access Protocol) [10], SAML [11], etc.

For providing efficient cross-organization web service under the standards above, identity management is necessarily implemented with intelligent way, not only for its feasibility, but also for its flexibility.

## 2.2 Cross-Organization Identity Management

The challenges to handle identity management in cross-organization web service are:

1. How to get global identity for required application in acceptable response time?
2. How to define the relationship among service organizations?
3. How to predict the address of service organization that the required global identity belong to, especially the required global identity can be "moved" to any service organization?

In web service, normally the scenario of service requested is defined as the following way:

1. A service requester is detected via client ID. Identity management process is started. In the identity management process, related identity document will be analyzed in terms of user's profile, service portfolio, privacy, authorization and transaction. The cache for recent contacting would be adopted for raising access performance.
2. If the global identity is analyzed through identity management and first service organization is hit, a service ticket will be generated and reply to the service requester. Go to 6.
3. Else if the global identity is confirmed that NOT belong to the first service organization, then the searching of right service organization will be run.
4. If right service organization for required global identity is found, then return the global identity back to first service organization, go to 6.

5. If right service organization cannot be found in time, then exceptional handling will be enabled.

6. No further cross-organization searching action will be required. Execute the application service with the delivered global identity.

## 3. INTELLIGENT XCS MODEL

XCS (eXtended Classifier System) was developed from LCS (Learning Classifier System) [4] and issued by Stewart W. Wilson in 1995. Classifier System [12] is the major research model for evolutionary computation in artificial intelligence. It is an intelligent learning mechanism with rules of expertise, messaging between rules and parallel process. Except the capability derived from LCS, XCS was also derived from related ZCS (Zeroth Level Classifier System) Research since 1994 [13][14] regarding to classifier system simplification.

By the characteristics of rules management, learning capability and evolutionary GA capability, XCS model is very suitable for representing prediction function in changeable environment as what we study in identity management.

### 3.1 The XCS Interactive Environment

As a classifier system, the interaction between XCS and environment was built on the information which can be depicted as the binary set way as below:

$$\sigma(t) \in \{0,1\}^L \dots\dots\dots (3.1)$$

In equation (3.1),  $\sigma(t)$  indicates the detected binary information in timing  $t$ ,  $L$  indicates the length of detected binary information. The action set for handling the detected information  $\sigma(t)$  can be expressed as the equation as below:

$$\alpha(t) \in \{a_1, \dots, a_n\} \dots\dots\dots (3.2)$$

In equation (3.2),  $\alpha(t)$  indicates the system action for handling  $\sigma(t)$  in timing  $t$ . Furthermore, for each  $\alpha(t)$ , the corresponded payoff  $\rho(t)$  will be generated. For different condition, the detected  $\sigma(t)$  is handled by one-step or multi-steps action. The flag eop will be set if  $\sigma(t)$  is processed completely in multi-steps action.

The rp (Reinforcement Program) [18], which was developed by Dorigo and Colombetti in 1998, will be enabled by payoff and eop which is set by XCS for handling  $\sigma(t)$  and  $\alpha(t)$ . Figure 3-1 indicates the interaction among XCS rule set, rp and Environment with related  $\rho(t)$ ,  $\sigma(t)$  and  $\alpha(t)$  [4]:

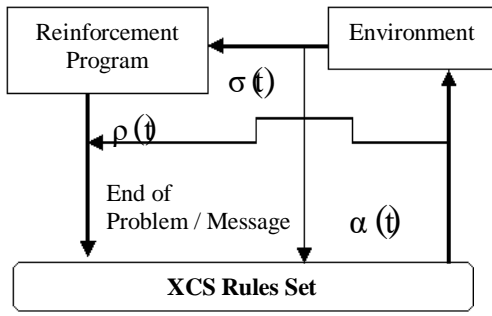

Figure 3-1: The Interaction among XCS Rule Set, rp and Environment with related  $\rho(t)$ ,  $\sigma(t)$  and  $\alpha(t)$

### 3.2 XCS Definition and Information Structure

The basic information structure in XCS is derived from normal classifier system which includes Condition, Action and Prediction (State), as table depicted in Figure 3-2:

Classifier									
Condition				Action		Prediction(State)			
1	0	#	1	0	1	0	1	0	1

Figure 3-2: The Basic Information Structure in XCS

However, XCS is more powerful than the traditional classifier system. More system parameters for XCS mechanism including Prediction error  $\epsilon$ , fitness function  $f$ , the counting variable  $exp$  of using corresponded XCS classifier in each action, the time stamps for last GA operation in action set, the size as of action set and the Numerosity num which is used for counts the numbers of micro classifiers under the appointed macro-classifier.

For any XCS Classifier  $cl$ , the attributes can be represented as :

$$x_{cl} \in \{C, A, p, exp, ts, as, num\} \dots \dots \dots (3.3)$$

In addition, XCS is also derived from LCS. According to LCS, the GA operation and learning mechanism in XCS classifier [19] follow MDSE (Markov Decision Support Environment) [20][21][22]. For NMDSE (Non-Markov Decision Support Environment) [23], some extended Internal-State registers were taken for handling learning operation and system evolution.

The XCS system parameters regarding to learning capability includes  $N$  (Size of XCS Population),  $\beta$  (Learning Rate),  $\alpha$  (Learning Coefficient),  $\epsilon_0$  (Precision of  $\epsilon$ ),  $v$  (Power Parameter),  $\gamma$  (Factor of Discount),  $\theta_{GA}$  (GA Threshold),  $\chi$  (Probability of Cross

Over),  $\mu$  (Probability of Mutation),  $\theta_{del}$  (Deletion Threshold),  $\delta$  (Expected Difference between Fitness and Prediction),  $\theta_{sub}$  (Threshold of Subsumption),  $P_{\#}$  (Probability of Adopting #:Don't Care in condition),  $p_I$ ,  $\epsilon_I$ , and  $f_I$  for initialize new XCS classifier,  $p_{explr}$  (Exploration Probability),  $\theta_{mna}$  (Threshold to Cover all Conditions [M]), doGASubsumption (Boolean Parameter If Offspring classifier will be tested when subsumption), doActionSetSubsumption (Boolean Parameter If Action Set will be tested when subsumption) that were defined in [4].

### 3.3 Generalization Hypothesis and System Behavior

Generalization Hypothesis, which was developed by Wilson, is one of the important system features in XCS [4]. The objective of generalization hypothesis is offering of "precise classifier sets" which got complete but non-repeated functional classifiers. The "precise classifier sets" must be as small as possible so that it improves the access performance in traditional classifier system. The Generalization was defined as below[20] :

§ Generalization : is viewed as the problem of finding the smallest set of rules (the classifiers) which completely and accurately represents the task that the agent has solved.

However, generalization is not easy to implement. Because generalization can be viewed as a minimization-covering problem so that normally it was treated as an NP problem [24]. Actually generalization was not a novel model. There were some literatures regarding to artificial intelligence was published for researching how to approach a definite generalization model [23][16]. Of course, XCS is one of the major models in generalization application [5].

With generalization, initialization process and XCS algorithm RUN EXPERIMENT was defined in message handling main loop [4].

According to the algorithm RUN EXPERIMENT, XCS behavior can be depicted as the figure 3-3 shown as below Figure 3-3.

However, for meeting the requirement of generalization, it would make an issue: How can XCS handle new input message  $\sigma(t)$  but no right classifier can offer right action?

For the issue mentioned above, 2 operations that can offer "covering" capability and handle the input new message are [4]:

1. Exploration : Actions are selected randomly.

2. Exploitation : always the most predictive action is selected.

For any new classifiers generated via exploration process, it will drive deletion actions for the weakest classifiers in XCS population [P].

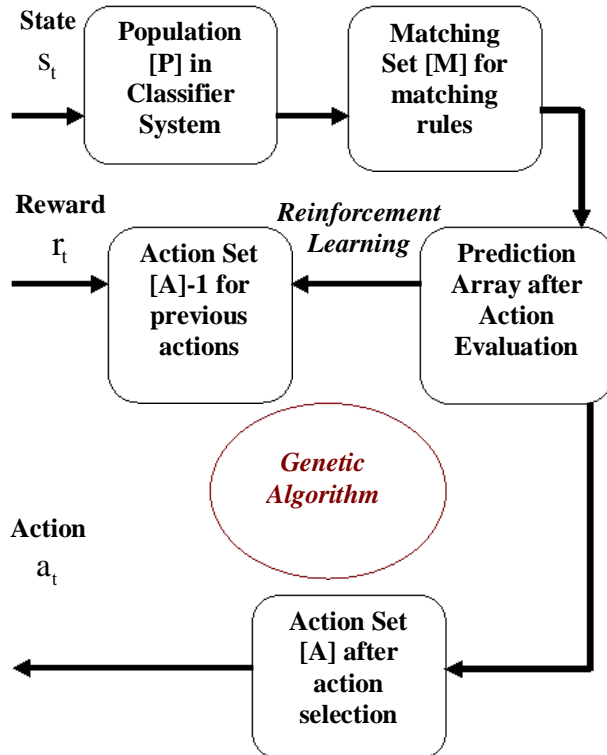

Figure 3-3: The XCS System Behavior

#### 4. XCS-BASED INTELLIGENT SEARCHING MODEL

In cross-organization internet environment, the first service organization which detects the requirement from client is not necessary the one which can offers right global identity for further application process. For the issue from global identity searching in cross-organization web service, XCS got the advantages from its flexible searching rules management, searching rules learning capability and self-evolutionary mechanism via GA operations.

Therefore, both attributes C and A are the key factors to express how to find right global identity for clients service request within input message  $\sigma$ . The information structure of  $\sigma$  is proposed as the data structure shown as figure 4-1:

Input Message $\sigma$			
Requested Event ID	Time Stamp	Client ID	Organization A

Figure 4-1: The Info. Structure of Input Message  $\sigma$

Regarding to input message  $\sigma$  in figure 4-1, the sub-field "Client ID" is the index to find the global

identity in cross-organization web service, sub-field "Organization A" is the target organization for finding global identity (Of course, if the value of "Organization A" is null, then more classifiers in XCS will be invoked to handle the input message  $\sigma$ ), the sub-field "Time Stamp" records the execution time which can be taken for verifying if the service scenario is right or not, and the sub-field "Requested Event ID" can be enumerated rely on the requirement of application. For example, in NP telecommunication service, the requested Event ID could be "Login", "Access Voice Mail", "Deliver Short Message", "Turn on service of don't disturb", etc., that may be required to execute cross-organization web service in m-commerce environment.

Following the principle of XCS operation, the input message  $\sigma$  will be handled by XCS main loop RUN EXPERIMENT ()[4].

On the other hand, regarding to the condition C in proposed XCS classifier, it can be represented as information in figure 4-2:

Condition C in XCS Classifier $x_{cl}$			
Condition Operator	Client ID	Organization X	P_Next Condition

Figure 4-2: The Information Structure of Condition C in XCS Classifier

In condition C of XCS classifier  $x_{cl}$ , the sub-field "Condition Operator" can be enumerated as the logical operators "NOT", "OR", "AND", "XOR", etc., that can integrated with more conditions in sub-field "P\_Next Condition". The sub-field "Client ID" is the private identity detected from client. The sub-field "Organization X" is the predicted target organization. The sub-field "P\_Next Condition" is the pointer which links to the possible next conditions in the other XCS classifier.

Also, the action A can be represented as information in figure 4-3:

Action A in XCS Classifier $x_{cl}$			
Action State	Action Type	Organization X	P_Next Action

Figure 4-3: The Information Structure of Condition C in XCS Classifier

In action A of XCS classifier  $x_{cl}$ , the sub-field "Action State" can be enumerated as "Action On", "Action Off", "Invalid", "In Action", etc., the sub-field "Action Type" can be enumerated as "Send", "Receive", "Initialize", etc., that will rely on the given application service requirement. The sub-field "Organization X" is the predicted target organization. The sub-field "P\_Next Action" is the pointer which links to more actions if necessary.

# Assessment of Service Quality of Logistics Center in Chain Stores Based on Fuzzy Logic and TOPSIS

Sheng Li

School of Business Administration, Southwestern University of Finance & Economics,  
Chengdu 610074, China

## ABSTRACT

In this paper, based on analysis of impact factors for service quality of logistics center in chains stores, a set of assessment indexes are proposed. Then, on the basis of this set of assessment indexes, two appraisal models are put forth: one is model based on TOPSIS, the other is fuzzy comprehensive assessment model. The experimental results demonstrate that the two novel methods are effective and feasible.

**Keywords:** Service quality, logistics center, assessment, ISM, fuzzy logic, TOPSIS

## 1. INTRODUCTION

If a chain store that wants to success constantly and keeps enhancing core competence, it is necessary to obtain and possess mighty competition fools. Effective logistics management is the key process for the sustainable development of chain stores. For managers usually want to get logistics competition superiority, it is significant to carry out and reinforce logistics management in chain stores. There are commonly seven individual functions in the logistics management of chain store: order, transport, inventory, packaging, warehousing, delivery, processing. And those functions act and impact themselves one another. It is well known that chain management aims at reducing the operation costs, high-efficiency operation and scale economy. The accomplishment of these objectives relied on the effective operation of logistics center. The pursuit for the objectives makes the management of chain stores more complex than that of traditional retail stores. So, it is important for researchers to pay attention to the operation of the logistics center in chain stores.

Service is the core function of the logistics center. In essence, only when free rein is given to the service function, the scale benefits may be reached fully. Thus, it is useful to study the service quality of logistics center. Whether the service quality can be accepted or not is due to customs, and whether they satisfy or not is the ultimate standard to evaluate the service level of the logistics center in a chain store. Satisfactory loyal customs construct the important parts of the core competence and source of benefits of a company. A scientific service quality approach is helpful to get accuracy data, information and the decision foundation and give advices on how to take some countermeasures to enhance service quality. Thus, we think that it is significant to set up a set of assessment indexes of service quality of logistics center and propose a comprehensive appraisal model respectively, which can help us monitor and analyze the operation state and reveal weaknesses of logistics center and give advices on planning and improving of logistics management in

a chain store perfectly.

There are so many impact factors for service level of a logistics center that there are difficulties in selecting the assessment indexes and decide the weights of them. As an effective system analysis tool, ISM (interpretive structural modeling) can help us grasp the chief factors and construct the hierarchy of assessment indexes. After expert survey and consulting, a set of assessment indexes of service quality of logistics center is put forward by using ISM and the corresponding hierarchy structure is set up here. Thus, the assessment problem becomes a multiple criterion decision-making problem in nature. So, what we should do is to establish appraisal model suing multiple attribute decision-making theory. In the work here, we provide two comprehensive appraisal models: one is model based on TOPSIS, the other is fuzzy comprehensive assessment model.

## 2 .ASSESSMENT INDEXES OF SERVICE QUALITY IN LOGISTICS CENTER

It is dispensable for carry out service quality assessment of logistics center using a scientific appraisal system in order to identify and analyze all the relative impact factors of it and give a corresponding assessment result. Here we propose a set of assessment indexes according to ISM on the basis of comprehensive considering such impact factors as feasibility, economy, hierarchy, time, consistency et al. The steps of ISM are as follows:

- (1) All experts and analysts discuss and select the elements in the system and establish an adjacent matrix.
- (2) Set up reachability matrix.
- (3) Carry out the further study and reasoning on the reachability matrix.
- (4) Conduct the region division and hierarchy division.
- (5) Acquire the reduced reachability matrix.
- (6) Gain the reachability matrix with minimum edges.
- (7) Draw a hierarchy directed graph.
- (8) Make the further analysis and discussion on the studied system.

After the steps abovementioned, we gain a set of assessment indexes of the service performance of a logistics center, which consists of six dimensions: 1) commodity availability; 2) scale economy; 3) information; 4) date of delivery; 5) after-sale service; 6) security. Moreover, each index can be further divided into other sub-indexes. Thus, a hierarchy of assessing service quality of a logistics center is constructed.

The corresponding indexes are listed as follows:

$$U = \{U_1, U_2, U_3, U_4, U_5, U_6\} \quad (1)$$

$$U_1 = \{u_{11}, u_{12}, u_{13}\} \quad (2)$$

$$U_2 = \{u_{21}, u_{22}, u_{23}, u_{24}\} \quad (3)$$

$$U_3 = \{u_{31}, u_{32}, u_{33}, u_{34}\} \quad (4)$$

$$U_4 = \{u_{41}, u_{42}, u_{43}\} \quad (5)$$

$$U_5 = \{u_{51}, u_{52}\} \quad (6)$$

$$U_6 = \{u_{61}, u_{62}\} \quad (7)$$

Where  $U$  is the set of assessment indexes for service quality of a logistics center,  $U_1$  is commodity availability,  $U_2$  is scale economy,  $U_3$  is information,  $U_4$  is date of delivery,  $U_5$  is after-sale service and  $U_6$  is security.  $u_{11}$  is commodity amount,  $u_{12}$  is commodity variety,  $u_{13}$  is commodity quality.  $u_{21}$  is the total value of commodity delivered,  $u_{22}$  is the total delivery cost,  $u_{23}$  is cost ratio,  $u_{24}$  is the cost of quick response.  $u_{31}$  is information convenience,  $u_{32}$  is information timeliness,  $u_{33}$  is information accuracy,  $u_{34}$  is initiative in information releasing.  $u_{41}$  is stableness in delivery timely,  $u_{42}$  is the ability of quick delivery,  $u_{43}$  is the capability in reducing lead time of delivery.  $u_{51}$  is returnability and  $u_{52}$  is treatment speed of customer complaints.  $u_{61}$  is goods safety and  $u_{62}$  is personal safety.

### 3. APPRAISAL MODEL USING TOPSIS

TOPSIS (Technique for order preference by similarity to ideal solution) is a simple and feasible decision method. By introducing ideal solution and negative ideal solution, the method is capable of reflecting the multiple attributions of thing to be appraised and its corresponding appraisal result is consistent with reality.

#### 3.1 Determine the Weights of Assessment Indexes Using AHP

The steps of determining the weights of assessment indexes using AHP are as follows:

#### Step 1. Construct comparison matrixes

Supposing that there are two sets  $U(n), V(m)$ .  $U$  is assessment item set which contents  $n$  elements,  $V$  is assessment indexes set which contents  $m$  elements. On the basis of analysis of the relationship among the  $m$  elements in the set  $V$ , we can get the hierarchic relationship of these assessment indexes. As for the indexes in a hierarchy, we can construct the judgment matrixes in each hierarchy according to the criterion they belong to. Here we assume that the judgment matrix is  $B$ ,  $B = (b_{ij})$ , where  $b_{ij}$  denotes the relative importance degree via pairwise comparison between index  $i$  and index  $j$ .

#### Step 2. Computation of weights of assessment indexes and testing consistency

As to each index judgment matrix  $B$ , characteristic root method is used to calculate weight vector under a single criterion. Then, carry out consistency testing and stochastic consistency testing of the judgment matrix. If the consistency testing value  $CI$  and stochastic consistency testing value  $CR$  are all less than 0.1, the judgment matrix is satisfied with the consistency condition, and the weights of indexes are reliable. Otherwise, adjust the judgment matrix and calculate weight vector again.

#### Step 3. Computation of weights of assessment indexes to the overall objective

On the basis of weight vectors in each hierarchy, by further computation we can get the comprehensive weights of each index with the overall objective.

### 3.2 Normalization of the Values of Assessment Indexes

According to the evaluation value of  $n$  elements in the assessment item set  $U$ , we can construct decision matrix  $A$ . In spite of the index is profitable type, cost type or range type, it should be transformed into profitable index at first. Thus, we have:

$$A = \begin{pmatrix} x_{11} & x_{12} & \dots & x_{1m} \\ x_{21} & x_{22} & \dots & x_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n1} & x_{n2} & \dots & x_{nm} \end{pmatrix} \quad (8)$$

Where  $x_{ij}$  is the appraisal value of the  $i$ th assessment item with respect to the  $j$ th index.

Normalize decision matrix  $A$ , we can acquire the normalized decision matrix  $Z$ .  $Z = (z_{ij})$ ,

$$i = 1, 2, \dots, n, \quad j = 1, 2, \dots, m,$$

$$\text{where } z_{ij} = x_{ij} / (\sum x_{ij}^2)^{1/2}.$$

### 3.3 Construct Normalized Matrix

Utilize the weight vector and the normalized decision matrix  $Z$ , we have the weighted normalized decision matrix  $V$  as follows:

$$V = ZW = \begin{pmatrix} v_{11} & v_{12} & \dots & v_{1m} \\ v_{21} & v_{22} & \dots & v_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ v_{n1} & v_{n2} & \dots & v_{nm} \end{pmatrix} \quad (9)$$

Where  $W$  is the comprehensive weight matrix of the  $m$  indexes by using AHP.

### 3.4 Decide the Ideal Points for Each Index

According to the weighted normalized decision matrix  $V$ , we can determine the positive ideal points and negative ideal points for each index. If index  $j$  is the profitable index, we assume:

$$v_j^+ = \max\{v_{ij} | i = 1, 2, \dots, n\} \quad j \in J \quad (10)$$

$$v_j^- = \min\{v_{ij} | i = 1, 2, \dots, n\} \quad j \in J' \quad (11)$$

Where  $v_j^+$  is the positive ideal solution and  $v_j^-$  is the negative ideal solution.

If index  $j$  belongs to cost type, we have:

$$v_j^+ = \min\{v_{ij} | i = 1, 2, \dots, n\} \quad j \in J \quad (12)$$

$$v_j^- = \max\{v_{ij} | i = 1, 2, \dots, n\} \quad j \in J' \quad (13)$$

Where  $v_j^+$ ,  $v_j^-$  have the same definition as in the formulae (10), (11).

### 3.5 Calculate the Distance to Ideal Points

Calculate the distance to the positive and negative ideal points of each item in the assessment item set  $U$ , and the corresponding formulae are as follows:

$$S_i^+ = \sqrt{\sum_{j=1}^m (v_{ij} - v_j^+)^2} \quad i = 1, 2, \dots, n. \quad (14)$$

$$S_i^- = \sqrt{\sum_{j=1}^m (v_{ij} - v_j^-)^2} \quad i = 1, 2, \dots, n. \quad (15)$$

Where  $S_i^+$  is the distance to positive ideal point and  $S_i^-$  is the distance to negative ideal point of each assessment item.

### 3.6 Calculate the Relative Access Degree

Calculate the relative access degree to the ideal points of each item in the assessment item set  $U$ , and sequence the elements in  $U$ . We have:

$$C_i = \frac{S_i^-}{S_i^+ + S_i^-} \quad i = 1, 2, \dots, n. \quad (16)$$

Where  $C_i$  is the relative access degree to the ideal points of each assessment item. According to value of  $C_i$ , we can sequence all items to be assessed. The higher  $C_i$  is, the better the item is.

## 4. APPRAISAL MODEL BASED ON FUZZY LOGIC

In the work here, we also formulate the appraisal of the service quality of a logistics center as a fuzzy MADM (multiple attributes decision-making) problem. We use fuzzy comprehensive assessment to achieve the final ranking scores of the service quality of logistics center. Fuzzy comprehensive assessment for a multi-layer system is to carry out comprehensive appraisal from the lowest layer to the uppermost layer step by step until the final assessment results in the uppermost layer is acquired. In the work here, what we should deal with is a three-layer system, the corresponding formulae are as follows:

$$S = W \circ R = W \circ \begin{pmatrix} \omega_1 \circ R_1 \\ \omega_2 \circ R_2 \\ \vdots \\ \omega_n \circ R_n \end{pmatrix} \quad (17)$$

Where “ $\circ$ ” is matrix product operator,  $W$  is the weight vector, and  $S$  is the vector of the final assessment result. As to the assessment in the second layer, the computation formula is:

$$R_i = \sum_{j=1}^m \omega_{ij} \circ R_{ij} \quad (18)$$

Where  $R_i$  is the assessment score of the factor  $U_i$  ( $i=1, 2, \dots, n$ ) in the hierarchy  $U$ , and  $\omega_{ij}$  is the weight of the factor  $u_{ij}$  under the criterion  $U_i$ ,  $m$  is the number of factors  $u_{ij}$  belongs to  $U_i$ ,  $R_{ij}$  is the membership vector for the factor  $u_{ij}$ , which can be gained by experts judgment and statistical method, and “ $\circ$ ” is matrix product operator.

$$S = W \circ R = \sum_{i=1}^n W_i \circ R_i = S(S_1, S_2, \dots, S_m) \quad (19)$$

Where  $S$  is the appraisal score of service quality of a logistics center, and  $W_i$  is the weight of the factor  $U_i$  belongs to  $U$ ,  $R_i$  is the assessment score of the factor  $U_i$  in the second layer, “ $\circ$ ” is matrix product operator and  $m$  is the number of assessment degrees. If  $S_k = \max(S_1, S_2, \dots, S_m)$ , then the service quality of the logistics center belongs to the degree  $k$ .

Namely, according to magnitude of  $S$ , we can make conclusions about the service quality of a logistics center. By using maximum membership principle, we can decide which grade a logistics center belongs to and sequence them quantitatively.

In this appraisal model, the weights of assessment indexes can be determined by using AHP as abovementioned.

## 5. APPLICATION

Based on the analysis process and assessment models abovementioned, we develop a computation procedure for the two models proposed above. Then, we apply this procedure to actual service quality assessment of logistics centers, and the corresponding results are shown in Table 1. The experimental results demonstrate that the assessment conclusion is reliable and is consistent with actual state, and it should be noted that the two models proposed here is feasible and have high precision and their computation results are identical each other.

**Table 1. Appraisal score for service quality of logistics center**

No.	Logistics center	Model using fuzzy logic		Model using TOPSIS	
		Score	Sequence	Score	Sequence
1	Trust mart	(0.21, 0.52, 0.13, 0.14)	1	0.742	1
2	Hongqi	(0.17, 0.20, 0.47, 0.16)	2	0.657	2
3	Huhui	(0.10, 0.23, 0.44, 0.23)	3	0.601	3
4	Shuangyang	(0.05, 0.19, 0.34, 0.42)	4	0.476	4

## 6. CONCLUSIONS

It is significant to appraise service quality of a logistics center occasionally, determine assessment indexes and their corresponding weights and get comprehensive evaluation score are indispensable. In this paper, a set of assessment indexes are proposed by using ISM. Then, two appraisal models are put forth: one is model based on TOPSIS, the other is fuzzy comprehensive assessment model. In the two models, the weight of each index is decided by using AHP. The experimental results demonstrate that the two novel methods are effective and feasible.

## ABSTRACT

We consider a supply chain with a single manufacturer selling a single product through two competing retailers. The manufacturer sets the wholesale price, and the retailers set the retail margin, simultaneously. The demand information among the members is asymmetric. The main contribution of this paper is extended the results of [5] with two competing retailers under asymmetric demand information. We consider six cases with the manufacturer or the retailers whether owning the information or not, and analyze these six cases in turn solve for a Bayesian equilibrium. Some results are obtained finally.

**Keywords:** supply chain, Channels of distribution, game theory.

## 1. INTRODUCTION

New market information technique, such as internet developing, B2C electronic commerce application and POS (point of sale) technique etc., making retailer can obtain the demand information of the end customers easily. But manufacturers have long been able to purchase similar information from the information consults company or by conducting marketing research themselves.

We consider a supply chain with a single manufacturer selling its single product through two competing retailers. The main purpose and contribution of this paper is extended the results of [5] with two competing retailers under asymmetric demand information. We examine this phenomenon through a game of asymmetric information played among a manufacturer and two competing retailers.

We denote  $a$  as the market scale (i.e., the maximum possible market demand) and assume that there is uncertainty over  $a$ . Let  $a$  be a random variable taking values in the finite interval  $[a_{\min}, a_{\max}]$ , with cumulative distribution function  $F$ . The expected value and variance of the variable  $a$  are  $\theta, \sigma^2$  respectively. This distribution function is known by all firms. When a firm does not have information about the demand parameter, it only knows  $F$ . However, if a firm acquires information, it knows the realization of the random variable,  $a$ .

The manufacturer sets the wholesale price  $w$ , and the retailers set the retail margin  $m_1, m_2$ , simultaneously. The retail price,  $p_i$ , is the sum of the wholesale price and the retail margin and is expressed as

$$p_i = w + m_i \quad (1)$$

Where  $w$  is the wholesale price and  $m_i$  is the retail margin.

We assume a linear demand function,

$$q_i = a - bp_i + dp_j \quad (2)$$

$$(i=1,2, i \neq j, 0 < d < b).$$

Where  $p_i$  is the price and  $q_i$  is the quantity demanded of the retailer  $i$ .

We also assume constant average cost of production, and cost of distribution, which are normalized to zero without loss of generality. All decision-makers are profit-maximizers and assumed to be risk-neutral.

The profit functions of the manufacturer ( $\Pi$ ) and the retailer  $i$  ( $\pi_i$ ) are derived by multiplying respective margins by quantity sold. They are, respectively

$$\Pi = \sum_{i=1}^2 w(a - bp_i + dp_j)$$

$$= w(2a - b - d)(2w + m_1 + m_2) \quad (3)$$

$$\pi_i = m_i(a - bp_i + dp_j) \quad (4)$$

$$i=1,2, i \neq j$$

Note that the two retailers have symmetric profit functions.

## 2. THE INTEGRATED BENCHMARK AND SYSTEM PROFIT

To establish a performance benchmark, we analyze the problem of an integrated firm. Now, if this supply chain is centrally owned and controlled, a vertically integrated manufacturer obtains the totality of channel profit: therefore, it will seek to maximize channel profit.

$$\Pi_{\bar{}} = p_1 q_1 + p_2 q_2$$

$$= p_1(a - bp_1 + dp_2) + p_2(a - bp_2 + dp_1) \quad (5)$$

The problem is concave, and table 1 shows the optimal profit.

### 3. EQUILIBRIUM ANALYSIS UNDER ASYMMETRIC DEMAND INFORMATION

We consider six cases: (1) case 1: None of the members knows the market scale  $a$ ; (2) case 2: All of the members know the market scale  $a$ ; (3) case 3: Only the Manufacturer knows the market scale  $a$ ; (4) case 4: Only the Retailers know the market scale  $a$ ; (5) case 5: Both the Manufacturer and the Retailer 1 know the market scale  $a$ , but Retailer 2 do not know; (6) case 6: Only the Retailer 1 knows the market scale  $a$ . We analyze these six cases in turn solve for an equilibrium.

#### 3.1 Case 1: None of the members knows the market scale $a$

In this case, although none of the channel members knows the exact value of the demand parameter,  $a$ , each maximizes expected profit taking into account the distribution of  $a$ . In particular, the expected profits of the manufacturer is given by

$$E[\Pi] = E[w(a - b(-d - m_1 + m_2))] \quad (6)$$

Differentiating equation (6) with respect to  $w$  and taking expectation over  $a$  gives the first-order condition below.

$$2\theta - b(-d - m_1 + m_2) = 0 \quad (7)$$

The expected profits of the retailer  $i$  is given by

$$E[\pi_i] = E[m_i(a - b(w + m_i) + d(w + m_j))] \quad i=1,2, i \neq j \quad (8)$$

Differentiating equation (8) with respect to  $m_i$  and taking expectation over  $a$  gives the first-order condition below.

$$\theta - b(w + 2m_i) + (d - w)m_j = 0 \quad i=1,2, i \neq j \quad (9)$$

Since we have a symmetric case  $m_1 = m_2$  in equilibrium, (8) and (9) gives

$$w = \frac{\theta b}{(3b - d)(b - d)} \quad (10)$$

$$m_1 = m_2 = \frac{\theta}{3b - d} \quad (11)$$

Substituting (10) and (11) into (6) and (8), we obtain the expected profits of the three members, see table 1.

#### 3.2 Case 2: All of the members know the market scale $a$ .

In this case, all of the channel members know the demand parameter. The first-order condition of the manufacturer is given by

$$2a - b(-d - m_1 + m_2) = 0 \quad (12)$$

The first-order condition of the retailer  $i$  is given by

$$a - b(w + 2m_i) + (d - w)m_j = 0 \quad (13)$$

By symmetry  $m_1 = m_2$ . Solving (12) and (13) gives

$$w = \frac{ab}{(3b - d)(b - d)} \quad (14)$$

$$m_1 = m_2 = \frac{a}{3b - d} \quad (15)$$

Substituting (14), and (15) into (6), and (8) gives and taking expectation over  $a$  gives the expected profits (table 1)

#### 3.3 Case 3: Only the Manufacturer knows the market scale $a$

This more complex case is a game of asymmetric information in which the manufacturer knows the demand scale,  $a$ , but the retailers only knows the distribution of  $a$ . Accordingly, a strategy for the manufacturer consists of a function  $w(a)$ , where wholesale price is contingent on the realized value of  $a$ , since the retailer does not observe  $a$ , the strategy for the retailer  $i$  consists of a fixed value of  $m_i$ . We are solving for a Bayesian equilibrium[5].

Since the manufacturer chooses a  $w(a)$  for each value of  $a$ , it maximizes (6). The first-order condition is given by

$$w(a) = \frac{a}{2(b - d)} - \frac{m_1 + m_2}{4} \quad (16)$$

Since the retailers know that the manufacturer's strategy is a function  $w(a)$ , the retailer  $i$  chooses  $m_i$  to maximize expected profit

$$E[\pi_i] = E[m_i(a - b(w(a) + m_i) + d(w(a) + m_j))] \quad (17)$$

Substituting (16) into (17) and take the first-order condition gives

$$w = \frac{a}{2(b - d)} - \frac{\theta}{2(3b - d)} \quad (18)$$

It is not difficult to obtain the profits of the three members (table 1).

Similarly, We analyze the other three cases in turn solve for a Bayesian equilibrium and obtain table 1.

Table 1 Individual and System Expected Profits

	$E[\Pi]$	$E[\pi_1]$	$E[\pi_2]$	System profit
Integrated channel	—	—	—	$\frac{\theta^2}{2(b-d)} + \frac{\sigma^2}{2(b-d)}$
Case 1	$S$	$T$	$T$	$S+2T$
Case 2	$S + \frac{2b^2\sigma^2}{(3b-d)^2(b-d)}$	$T + \frac{b\sigma^2}{(3b-d)^2}$	$T + \frac{b\sigma^2}{(3b-d)^2}$	$S+2T + \frac{2b(2b-d)\sigma^2}{(3b-d)^2(b-d)}$
Case 3	$S + \frac{\sigma^2}{2(b-d)}$	$T$	$T$	$S+2T + \frac{\sigma^2}{2(b-d)}$
Case 4	$S$	$T + \frac{b\sigma^2}{(2b-d)^2}$	$T + \frac{b\sigma^2}{(2b-d)^2}$	$S+2T + \frac{2b\sigma^2}{(2b-d)^2}$
Case 5	$S + \frac{\sigma^2}{2(b-d)}$	$T$	$T$	$S+2T + \frac{\sigma^2}{2(b-d)}$
Case 6	$S$	$T + \frac{\sigma^2}{4b}$	$T$	$S+2T + \frac{\sigma^2}{4b}$

Where  $S = \frac{2b^2\theta^2}{(3b-d)^2(b-d)}$ ,  $T = \frac{b\theta^2}{(3b-d)^2}$

#### 4. RESULTS

We denote the expected profit of the manufacture under case  $i$  as  $E[\Pi]_{ci}^*$ , and the expected profit of retailer  $j$  under case  $i$  as  $E[\pi_j]_{ci}^*$ . We have following results

**Result 1** (1)  $E[\Pi]_{c1}^* = E[\Pi]_{c4}^* = E[\Pi]_{c6}^* < E[\Pi]_{c2}^* < E[\Pi]_{c5}^* < E[\Pi]_{c3}^*$

(2)  $E[\pi_1]_{c1}^* = E[\pi_1]_{c3}^* < E[\pi_1]_{c2}^* < E[\pi_1]_{c5}^* < E[\pi_1]_{c6}^* < E[\pi_1]_{c4}^*$

(3)  $E[\pi_2]_{c1}^* = E[\pi_2]_{c3}^* = E[\pi_2]_{c5}^* = E[\pi_2]_{c6}^* < E[\pi_2]_{c2}^* < E[\pi_2]_{c4}^*$

If retailer  $i$  has the full information about  $a$  and can report the information to retailer  $j$  without any cost, then retailer  $i$  desires to tell retailer  $j$  about  $a$  to increase own profit when the manufacture has no information concerning  $a$ . When the manufacture has the full information about  $a$ , retailer  $i$  has no incentive to do so.

**Result 2** (1) When the manufacturer is unaware of  $a$ , its expected profit  $E[\Pi]^* = \frac{2\theta^2 b^2}{(3b-d)^2(b-d)}$ .

(2) When Retailer  $i$  is unaware of  $a$ , its expected profit

$$E[\pi_i]^* = \frac{\theta^2 b}{(3b-d)^2}.$$

**Result 3** Total channel profits are highest when the supply chain is vertically integrated; the next in order for only the manufacturer knows the market information. While all members do not know the information, the system profit is minimum.

Although the manufacturer is not a leader in the game, Result 2 expresses the manufacturer to be placed in the predominant position in the supply chain.

**Result 4** (1) When the supply chain is vertically integrated, the expected distribution quantity is  $q_1+q_2=\theta$ . Otherwise, the expected distribution quantity is

$$q_1=q_2=\frac{\theta b}{3b-d} \quad (2) \text{ When the supply chain is vertically}$$

integrated, the expected price is  $p_1^* = p_2^* = \frac{\theta}{2(b-d)}$ .

Otherwise, the expected price is

$$p_1 = p_2 = \frac{\theta(2b-d)}{(3b-d)(b-d)}.$$

Since  $0 < d < b$  and  $\frac{2\theta b}{3b-d} < \theta$ , when the supply chain is vertically integrated, the expected distribution quantity is maximum.

## ABSTRACT

Based on the work of Krishna and Rosenthal (1996) about combinatorial auctions bidding equilibrium analysis and Che(1993)'s research about one-unit multi-attributes auctions, we construct a multi-attributes procurement simultaneous auction for 2 objects, through a first-score(price), sealed-bid format. There are two kinds of bidders: *simple bidders* and a *diverse bidder* considered in this model. Each *simple bidder* is interested in only one of the objects, while the *diverse bidder* is interested in both. With some further assumptions, we finally obtain the equilibrium bidding strategies for the both two kinds of bidders.

**Keywords:** Bidding Strategies, Procurement, Combinatorial Auctions

## 1. INTRODUCTION

Many auctions involve the sale (or purchase) of a variety of distinct assets. Examples are auctions for airport time slots, delivery routes and FCC radio spectrum rights. Because of complementarities (or substitution) between the auctioned assets, bidders have preferences not just for particular items but for sets or bundles of items. For this reason, economic efficiency is enhanced if bidders are allowed to bid on bundles or combinations of different assets. Possibly because of FCC combinational auction, auctions where bidders submit bids on combinations have recently received much attention [Rothkopf et. al.(1998), Sandholm (1999)]. Actually, such auctions were proposed as early as 1976, by Jackson, for radio spectrum rights. Increases in computing power have made them more attractive to implement. The value of assets for a particular bidder, may depend strongly on which other assets she wins. Because of the possibility of such synergy, the auction designers require attentions to allowing bids not just for individual asset, but also bids for the combinations of assets, which is called combinational auctions (CAs). When an auctioneer procure items by auctions, she may allow the potential suppliers to bid for various products bundles, which is called Procurement Combinatorial Auctions. It will make variety multi-units procurement much fairer, more feasible and more efficient.

One of the most challenging problems in Procurement CAs is Winners Determination Problem (WDP). The general allocation problem in combinational auctions can be commonly formulated as an integer programming problem which is computationally intractable. Literature about CAs mechanism design is quite rich [e.g., Krishna and Rosenthal, 2000; Parkes, 2001,]. Cantillon and Pesendorfer (2003) consider the problem of identification and estimation in the first price multi-unit auction. The topics on one-unit auctions' bidding strategies and winning probability are abundantly addressed. However, discussions about CAs bidding strategies are inadequate. Krishna and Rosenthal (1996) considered situations where multiple

objects are auctioned simultaneously by means of a second-price sealed-bid auction, and derived the bidding equilibrium strategies for the synergy bidder. Rosenthal and Wang (1996) studied a simultaneous-auction model with synergies, common values, and constructed strategies in which bidders of different types randomize over different bid intervals, also provided necessary and sufficient conditions for such equilibria strategies. Che (1993) studies design competition in procurement by developing a model of two-dimensional (price and quality) auctions, and corresponding bids are evaluated by a scoring rule designed by auctioneer. In this paper, we will discuss bidding strategies in a specific multi-attributes procurement CA setting.

## 2. MODEL AND ITS ASSUMPTIONS

In this model, there are 2 objects to be procured by an auction simultaneously through a first-price, sealed-bid format. And two kinds of bidders, i.e. *simple bidder* and *diverse bidder* are considered. Each *simple bidder* is interested in only one of the objects, while the *diverse bidder* is interested in two objects. For each of the 2 objects, there are  $n$  interested *simple bidders*. Each *simple bidder* has a privately known supply cost function for the object.

Other assumptions and their mathematical expressions are below:

(1) Bidding vector is  $\{p, q\} \in R_+^2$ ,  $p$  and  $q$  denote bidding price and supply quality separately. Especially, quality, in our model, is a unified number to measure all non-price factors of the objects. The scoring function of the bidding vectors has quasi-linear form

$$S(q, p) = s(q) - p \quad (1)$$

where  $s(\cdot)$  is strictly increasing with respect to  $q$ .

(2) Number of *simple bidders* for each object is  $n$ , only one *diverse bidder* in the basic model.

(3) The cost functions of *simple bidders* are

$$c(q, \theta_i) = \begin{cases} c_1(q, \theta_i), & \text{if bid item 1} \\ c_2(q, \theta_i), & \text{if bid item 2} \end{cases},$$

where  $\theta_i$  denotes type of *simple bidder*  $i$ , which is private information of bidder  $i$ , and  $\theta_i$  is drawn from interval  $[\underline{\theta}, \bar{\theta}]$  with identical distribution  $F(\cdot)$  which are common knowledge.  $c_1(\cdot, \cdot)$  and  $c_2(\cdot, \cdot)$  are increasing with respect to  $q$  and  $\theta_i$ . Type parameter of the *diverse bidder* is denoted as  $\theta$  which is drawn from interval  $[\underline{\theta}, \bar{\theta}]$  with the identical distribution  $F(\cdot)$ ,  $\theta$  is also private information, the cost functions of the *diverse bidder* are  $c_1(q, \theta)$  for object 1 and  $c_2(q, \theta)$  for object 2.

(4) Profit of *simple bidder*  $i$ , with bid  $\{p, q\} \in R_+^2$ , is denoted as

$$\pi_i(q, p) = p - c_r(q, \theta_i), r=1, 2 \quad (2)$$

Profit of the *diverse bidder*, with bid  $\{p, q\} \in R_+^2$ , is

$$\begin{cases} p_1 - c_1(q, \theta), & \text{get item 1} \\ p_2 - c_2(q, \theta), & \text{get item 2} \\ p_1 - c_1(q, \theta) + p_2 - c_2(q, \theta) + \alpha, & \text{get both} \end{cases} \quad (3)$$

where  $\alpha$  is a non-negative constant which is *diverse bidder's* private information.

### 3. BIDDING STRATEGY ANALYSIS

Let  $S_0(\theta) \equiv \max[s(q) - c(q, \theta)]$  for all  $\theta \in [\underline{\theta}, \bar{\theta}]$ , by using envelope theorem, we know  $S_0(\cdot)$  a strictly decreasing function, therefore its inverse function exists. Let  $v \equiv S_0(\theta)$ ,  $v$  can be regarded as scoring capability of supplier. Let  $H(v) \equiv 1 - F(S_0^{-1}(v))$ , then distribution  $F(\cdot)$  of  $\theta$  is transformed into distribution  $H(\cdot)$  of  $v$ , which also imply that the one-to-one mapping from  $v$  to  $\theta$ .

Let  $b \equiv S(q_s(\theta), p)$ , where  $q_s(\theta) = \arg \max[s(q) - c(q, \theta)]$ , and  $b$  is the score of the bidding by supplier with type parameter  $\theta$ . Let  $B(\cdot)$  denote the scoring function with the independent variable  $v$ , and  $B(\cdot)$  is strictly increasing with  $v$ . Note that  $p - c(q(\theta), \theta) = v - b$ , then we have the expected revenue of any *simple bidder* with type  $\theta_i$  and quality bidding  $q_s(\theta_i)$ :

$$\begin{aligned} \pi(q(\theta_i), p | \theta_i) &= [p - c(q(\theta_i), \theta_i)] \\ &\times \text{prob}\{\text{win} | S(q(\theta_i), p)\} \\ &= [v - b] \{H(B^{-1}(b))\}^n \end{aligned} \quad (4)$$

where  $\text{prob}\{\text{win} | S(q(\theta_i), p)\}$  represents the winning probability of bidder whose bidding is  $\{q(\theta_i), p\}$ .

Therefore, Any *simple bidder* with type  $\theta_i$  has the following bidding equilibria strategy [Riley and Samuelson, 1981; Che, 1993,]:

$$\begin{cases} q(\theta_i) = \arg \max[s(q) - c_r(q, \theta_i)], & r=1 \text{ or } 2 \\ p(\theta_i) = c(q, \theta_i) + \int_{\theta_i}^{\bar{\theta}} c(q(t), t) \left[ \frac{1 - F(t)}{1 - F(\theta_i)} \right]^n dt \end{cases} \quad (5)$$

It is convenient to define

$$L(b) = \{H(B^{-1}(b))\}^n \quad (6)$$

Intuitively,  $L(b)$  is the probability of *diverse bidder* to win item 1 (or item 2) with score  $b$ , that is, the probability of all the *simple bidders* who are interested in item 1 (or item 2) get score less than  $b$ .

We've already known the *simple bidder* will use the bidding strategy in (5). Therefore, the expected revenue of *diverse bidder* with type  $\theta$  is

$$\begin{aligned} \pi(S_1(q_1(\theta), p_1), S_2(q_2(\theta), p_2) | \theta) \\ = L(S_1) L(S_2) [(p_1 - c_1) + (p_2 - c_2) + \alpha] \\ + L(S_1)(1 - L(S_2))(p_1 - c_1) \\ + L(S_2)(1 - L(S_1))(p_2 - c_2) \end{aligned} \quad (7)$$

In the above equation, first term is the expected revenue of winning both items, while the last two terms separately corresponds to expected revenue of winning only item 1 or only item 2.

**Lemma 1.** The *diverse bidder* with type  $\theta$  follows the bidding strategy whose quality-bid  $(q_{1s}(\theta), q_{2s}(\theta))$  respectively is

$$\begin{aligned} q_{1s}(\theta) &= \arg \max[s(q) - c_1(q, \theta)] \\ q_{2s}(\theta) &= \arg \max[s(q) - c_2(q, \theta)] \end{aligned} \quad (8)$$

**Proof.** Assume there exists another equilibrium strategy  $\{(q_1, p_1), (q_2, p_2)\}$ , and  $q_1 \neq q_{1s}, q_2 \neq q_{2s}$ ,

Then construct a bid  $\{(q_1', p_1'), (q_2', p_2')\}$ , where

$$\begin{aligned} q_1' &= q_{1s}, \\ q_2' &= q_{2s}, \\ p_1' &= p_1 + s(q_{1s}) - s(q_1), \\ p_2' &= p_2 + s(q_{2s}) - s(q_2) \end{aligned} \quad (9)$$

Note

$$\begin{aligned} S(q_1', p_1') &= S(q_1, p_1) = S_1, \\ S(q_2', p_2') &= S(q_2, p_2) = S_2 \end{aligned} \quad (10)$$

Then, with bid  $\{(q_1', p_1'), (q_2', p_2')\}$ , the expected revenue of diverse bidder is below,

$$\begin{aligned} &\pi((q_1'(\theta), p_1'), (q_2'(\theta), p_2') | \theta) \\ &= L(S_1) L(S_2) \{ (p_1 - c_1(q_1) + [s(q_{1s}) - c_1(q_{1s}) \\ &\quad - (s(q_1) - c_1(q_1))] + (p_2 - c_2(q_2) \\ &\quad + [s(q_{2s}) - c_2(q_{2s}) - (s(q_2) - c_2(q_2))] + \alpha \} \\ &\quad + L(S_1)(1 - L(S_2)) \{ (p_1 - c_1(q_1) \\ &\quad + [s(q_{1s}) - c_1(q_{1s}) - (s(q_1) - c_1(q_1))] \} \\ &\quad + L(S_2)(1 - L(S_1)) \{ (p_2 - c_2(q_2) \\ &\quad + [s(q_{2s}) - c_2(q_{2s}) - (s(q_2) - c_2(q_2))] \} \end{aligned} \quad (11)$$

Note

$$q_{1s}(\theta) = \arg \max_q s(q) - c_1(q, \theta)$$

$$\text{and } q_{2s}(\theta) = \arg \max_q s(q) - c_2(q, \theta)$$

therefore,

$$\begin{aligned} &\pi((q_1'(\theta), p_1'), (q_2'(\theta), p_2') | \theta) \\ &> L(S_1) L(S_2) [(p_1 - c_1(q_1)) \\ &\quad + (p_2 - c_2(q_2)) + \alpha] + L(S_1)(1 - L(S_2)) (p_1 - c_1(q_1)) \\ &\quad + L(S_2)(1 - L(S_1)) (p_2 - c_2(q_2)) \end{aligned} \quad (12)$$

Thus, we have

$$\begin{aligned} &\pi((q_1'(\theta), p_1'), (q_2'(\theta), p_2') | \theta) \\ &> \pi((q_1(\theta), p_1), (q_2(\theta), p_2) | \theta) \end{aligned} \quad (13)$$

This completes the proof.  $\square$

From LEMMA 1 and (7), we know the optimization problem of diverse bidder with type  $\theta$  can be expressed as follows:

$$\begin{aligned} &\max_{p_1 p_2} \pi((q_{1s}(\theta), p_1), (q_{2s}(\theta), p_2) | \theta) \\ &= \max_{p_1 p_2} \{ L(s(q_{1s}(\theta)) - p_1) L(s(q_{2s}(\theta)) - p_2) \\ &\quad [(p_1 - c_1(q_{1s}(\theta))) + (p_2 - c_2(q_{2s}(\theta))) + \alpha] \\ &\quad + L(s(q_{1s}(\theta)) - p_1)(p_1 - c_1) \\ &\quad \times (1 - L(s(q_{2s}(\theta)) - p_2)) \\ &\quad + L(s(q_{2s}(\theta)) - p_2)(p_2 - c_2) \\ &\quad \times (1 - L(s(q_{1s}(\theta)) - p_1)) \} \end{aligned} \quad (14)$$

Generally, the pairwise point  $(p_1, p_2)$  which satisfies

the first order condition and the second order condition of (14), is the solution to the maximal expected revenue. Now restrict attention to equal-bid for two identical objects, that is, item 1 and item 2 are the same. Naturally, we can let

$$q_{1s}(\theta) = q_{2s}(\theta) = q_s(\theta)$$

$$\text{and } c_1(q_s(\theta)) = c_2(q_s(\theta))$$

By LEMMA 1, the quality-bid,  $q_s(\theta)$ , in equilibrium strategy is uniquely determined by  $\theta$ , then the corresponding cost  $c(q_s(\theta))$  is also determined by  $\theta$  uniquely. Now, define optimal cost of bidder with type  $\theta$  as

$$c^*(\theta) = c_1(q_s(\theta)) = c_2(q_s(\theta))$$

Thus rewrite (14) as

$$\begin{aligned} &\max_p \pi((q_s(\theta), p), (q_s(\theta), p) | \theta) \\ &= \max_p \{ (L^2(s(q_s(\theta)) - p) \times (2(p - c^*(\theta)) + \alpha) \\ &\quad + 2L(s(q_s(\theta)) - p)(p - c^*(\theta)) \\ &\quad \times (1 - L(s(q_s(\theta)) - p)) \} \end{aligned} \quad (15)$$

Without loss of generality, let  $s(q_s(\theta))$  equal 1, and assume price  $p$  is drawn from  $[0, 1]$ . Define

$$G(.) \equiv H(B^{-1}(.) \text{ and rewrite (15) as}$$

$$\begin{aligned} &\max_p \pi((q_s(\theta), p), (q_s(\theta), p) | \theta) \\ &= \max_p \{ (G^{2n}(1 - p) \times (2(p - c^*(\theta)) + \alpha) \\ &\quad + 2G^n(1 - p)(1 - G^n(1 - p))(p - c^*(\theta)) \} \end{aligned} \quad (16)$$

By first derivative of (16) with respect to  $p$ , we have

$$\frac{dp}{dp} = -\alpha G^n(1 - p) + p \frac{1}{n} G(1 - p) \theta c^*(\theta) = 0 \quad (17)$$

Now considering the relationship between the optimal cost of diverse bidder with type  $\theta$ , i.e.,  $c^*(\theta)$ , and her price bid  $p$ , from (17) we have

$$c^*(\theta) = \alpha G^n(1 - p) - p \frac{1}{n} G(1 - p) \quad (18)$$

Actually, (18) is the correspondence from optimal cost  $c^*(\theta)$  to optimal price bid  $p$ , and we can abstractly

express (18) as  $c^*(\theta) = c_p(\theta)$ . The only special feature used in the argument is that function  $c_p(s)$  convex.

Generally, convexity of  $c_p(.)$  is not easy to characterize in terms of the primitive assumptions of our model. However, if  $G(.)$  is uniform distribution, i.e., the distribution of production capability  $v$  is uniform, then the function  $c_p(.)$  is indeed convex. If  $c_p(.)$  is not convex, the situation becomes more complicated and not worth pursuing here. Therefore, there exist at most 2 roots of equation (18).

Corresponding to different optimal cost  $c^*(\theta)$ , denote  $p(c^*(\theta))$  as the solutions of (17). Define  $p^*(c^*(\theta))$  as the unique root or greater one of the two roots, i.e.,

$$p^*(c^*(\theta)) = \begin{cases} p(c^*(\theta)), & \text{for unique solution} \\ \max\{p(c^*(\theta))\}, & \text{for other case} \end{cases} \quad (19)$$

By convexity of  $c_p(\cdot)$ , it's easy to know  $d\pi/dp = -\alpha G^n(1-p) + p G(1-p)/n + c^*(\theta)$  is concave. Therefore, the derivative of  $d\pi/dp$  is non-positive at the point of the greater root. That means the second derivative of expected revenue with respect to  $p$ , at the greater root, is non-positive, i.e.,  $\pi''(p^*(c^*(\theta))) < 0$ . It is the second-order sufficient condition for local maximizer. Consequently, we are sure that  $p^*(c^*(\theta))$  is the local maximizer, while the smaller root is not.

Since the domain of expected revenue (16) is closed set, in order to find global maximizer, what we should do is to compare the boundary solutions with interior solution. Next, define a  $\hat{c}(\theta)$  as follows,

$$\hat{c}(\theta) = \max\{c^*(\theta) \mid \pi(0|c^*(\theta)) - \pi(p^*(c^*(\theta))|c^*(\theta)) \geq 0\} \quad (20)$$

and

$$\frac{d\{\pi(0|c^*(\theta)) - \pi(p^*(c^*(\theta))|c^*(\theta))\}}{dc^*(\theta)} = -2(1-p) \leq 0 \quad (21)$$

It follows that if there exists  $\hat{c}(\theta)$ , such that

$$\pi(0|\theta) - \pi(p^*(c^*(\theta))|\theta) \geq 0$$

then for all  $c^*(\theta): 0 < c^*(\theta) < \hat{c}(\theta)$  we have

$$\pi(0|\theta) - \pi(p^*(c^*(\theta))|\theta) \geq 0 \quad (22)$$

Essentially, in order to compare boundary solutions with interior solutions, we need to define  $\hat{c}(\theta)$ . In other words,  $\hat{c}(\theta)$  is the *separating point* in which boundary solution is better than interior solution, and the following result is immediate.

**Theorem 1.** *The following constitutes an equilibrium of our Multi-attributes procurement auction model.*

The simple bidders with type  $\theta_i$  follow the strategy:

$$\begin{cases} q(\theta_i) = \arg \max [s(q) - c_r(q, \theta_i)], r = 1 \text{ or } 2 \\ p(\theta_i) = c(q, \theta_i) + \int_{\theta_i}^{\bar{\theta}} c(q(t), t) \left[ \frac{1 - F(t)}{1 - F(\theta_i)} \right]^n dt \end{cases} \quad (23)$$

The diverse bidder with type  $\theta$  follows the strategy:

Case 1: For any given  $c^*(\theta)$ , there exists a unique solution to (17)

$$\begin{cases} q_s(\theta) = \arg \max [s(q) - c(q, \theta)] \\ p(\theta) = p(c^*(\theta)) \end{cases} \quad (24)$$

Case 2: For any given  $c^*(\theta)$ , there exist two solutions to (17)

$$\begin{cases} q_s(\theta) = \arg \max [s(q) - c(q, \theta)] \\ p(\theta) = \begin{cases} p^*(c^*(\theta)) & \text{if } c^*(\theta) > \hat{c}(\theta) \\ 0 & \text{if } 0 < c^*(\theta) < \hat{c}(\theta) \end{cases} \end{cases} \quad (25)$$

#### 4. CONCLUSION REMARKS

In this paper, we construct a multi-attributes procurement simultaneous auction for 2 objects, through a first-score (price), sealed-bid format. There are two kinds of bidders, *simple bidder* and *diverse bidder*, are considered in our model. Each *simple bidder* is interested in only one of the objects, while the *diverse bidder* is interested in both. With some assumptions, we obtain the equilibrium bidding strategies for the both two kinds of bidders. Basically, the difference between ours work and past correlated research (Krishna and Rosenthal (1996)) are: multi-attributes vs. single attribute (price), first-score(price) vs. second-price, and, most important, procurement auction vs. selling auction. Also, this piece of research can not be realized without Che (1993)'s work about one-unit multi-attributes procurement auction. This work could be regarded as a first step of constructing equilibria and designing mechanism for multi-attributes procurement combinatorial auctions. Future work includes extensions to multiple *diverse bidders* in primal model, and heterogeneous items assumption. It may also be interesting to study collaboration and competition relationship between bidders in multi-attributes procurement combinatorial auctions, in more general or practical environment, which could be undertaken on the basis of this work.

## Business Interactions with Web Services

Youcef Baghdadi

Department of Computer Science, Sultan Qaboos University, PO Box 36, PC 123 Al-Khod, Oman  
ybaghdadi@squ.edu.om

### ABSTRACT

Business interactions require technologies with attractive features to dynamically connecting enterprise information systems and external applications. This work presents a framework of business interactions that consists of: (1) a conceptual architecture view, (2) a technical architecture view, and (3) an implementation architecture view of business interactions. The conceptual view defines and categorizes business interactions into enterprise interactions, partners' interactions and customers' interactions. The categorization allows deciding and deploying the technical view that specifies the required connections for EAI, CRM, B2C and B2B. The implementation view shows how the features of Web services, a connecting technology, enables any kind of specified business interactions. Web services features allow first unlocking and adding value to existing enterprise assets such data and applications; then dynamically connecting them into new solutions such as business processes that respond to business events or changes in business conditions.

**Key Words:** Business Interactions, Framework, EAI, CRM, B2C, B2B, e-Business, Integration, Web Services, SOA.

### 1. INTRODUCTION

Businesses need to adapt rapidly and cost-effectively to new businesses events and conditions, namely customers and partners demand and behavior. This requires technologies that enable cost-effective and dynamic interactions within and especially across the boundaries of the enterprise. However, to deploy any technology, one must abstract the business according to different but related perspectives such as in [16]. This work concerns with a business interactions perspective, namely a framework with three views of business interactions in order to decide and deploy a technology with attractive features, namely connecting cost-effectively existing assets in terms of data and applications.

The framework aims mainly at providing business interactions oriented architecture that considers both business perspective and IT perspective in order to point up design as well as technical issues that may hinder the deployment of business interactions enabling technology. That is, Web services.

The framework consists of three architectural views of business interactions perspective that are:

1) The conceptual view architecture aims at specifying the business interactions regardless of the implementing technology. The conceptual view architecture defines, specifies and categorizes business interactions into customers' interactions, enterprise interactions and partners' interactions. This categorization allows a specification of each category of interactions in order to decide an appropriate enabler technology for respectively EAI, CRM, B2C, B2B, and ultimately dynamic e-business.

2) The technical view architecture aims at identifying: (i) the existing enterprise informational as well as computational assets (e.g. existing applications, integration applications and middleware), (ii) the existing (or to develop) connections between the enterprise assets and external applications, and (iii) the requirements and features of the connecting technology. The technical view focuses on technological requirements to fill the business processes breakups that require connections.

3) The implementation view architecture specifies how Web services technology, the *de facto* integration standard [1]; and also the *de facto* Internet standard instance of the services-oriented architecture (SOA) [2][14], presents attractive features in terms of cost-effective connections within and across the enterprise, i.e. between the enterprise and its customers/partners to enable EAI, CRM, B2C, B2B, and ultimately dynamic e-business. Web services technology is, by essence, a connections technology. Indeed, the underlying standards of such a technology, namely, XML, WSDL, UDDI, WS-I, BP4WS, SOAP and other related to security and transactions when matured will allow: (1) interfacing the enterprise assets that are data and applications as services in order to unlock them, (2) publishing the interfaces in a registry to be discovered and reused, (3) discovering the services, (4) connecting (statically or dynamically) any application to the services, (5) ultimately connecting services to each other with respect to SOA architecture, and (6) composing dynamically the services into new solution to respond to business events or changes.

### 2. CATEGORIZATION OF INTERACTIONS

Due to organizational and technical constraints, business processes are broken up into causal and reciprocal activities. That is, the set of activities form a

flow where each activity takes an input from a provider and serves an output to a consumer. These business processes breakups require a set of business interactions, which are generally implemented by organizational and technological artifacts. Therefore, one needs to abstract these interactions in order to first specify them with respect to a business perspective before to come to a technology perspective. The abstraction allows deciding an appropriate technology that enable cost-effective and dynamic interactions.

## 2.1 Business Interactions

The concept of interactions has been specified by different disciplines. A business perspective specification, we adapt from different disciplines, considers interactions as a set of reciprocal (or causal) activities performed by local or remote providers and consumers in a synchronous or asynchronous manner. Each of them has a certain degree of autonomy and freedom (e.g. to leave at any time). Therefore, business interactions are characterized by space, time, and dynamics. Moreover, providers and consumers interact in different situations.

*Space.* Interactions involve local as well as distributed and remote providers and consumers.

*Time.* Action-reactions of the providers and consumers are temporal, synchronous as well as asynchronous.

*Dynamics.* While interactions in goal-driven businesses are often rigid and fixed (e.g. mechanisms of coordination used to offset planned task allocation in goal-driven businesses). Interactions, in event-driven businesses, are dynamic relationships among autonomous providers and consumers.

*Situations.* Situations of interactions are answer to 'why do providers and consumers interact?' With respect to a business (and information systems) perspective. Business providers and consumers interact for numerous reasons, namely:

- Internal and external exchanges of information.
- Synergy of business processes.
- Unlocking informational (e.g. data) and computational resources (e.g. applications).
- Emergent knowledge. Indeed, knowledge resulting from interactions is more relevant and more complete than simple knowledge integration.

## 2.2 Categorization of Business Interactions

In addition to their specification with respect to space, time, dynamics, and situations, it is a must to categorize business interactions while deciding and deploying enabler technologies. First, business interactions differ according to the types of the involved providers/consumers, and the types of business processes and business events. Indeed, local

business interactions are different from interactions with partners and customers. Moreover, the business interactions of a goal-driven business differ from those of an event-driven business. Second, business interactions will not have the same priority with respect to the enabling technology. For, instance, EDI technology may be suitable for a long term fixed relationship between a business and its partners. Whereas Web services technology allows a real dynamic relationship between a business and its partners. Third, interactions between a business and its partners/customers are based on the effectiveness of internal interactions. That is, one cannot design and implement external interactions if the local ones are not working properly. For instance, B2B cannot be approached if EAI is not working properly. Figure 1 distinguishes each of the following categories of business interactions:

- 1) Interactions between business and its customers (**C-B**).
- 2) Internal (enterprise) interactions that are:
  - Interactions between enterprise (local) primary processes (**P-P**).
  - Interactions between local primary and supporting processes (**P-S**).
  - Interactions between local business process activities (**AT**). These are required when a local business process is decomposed (**A-A**).
  - Interactions between business processes and the business objects (or coordination artifacts) as presented in the different information systems and legacy systems.
- 3) Interactions across businesses, i.e. interactions between business processes that cross the boundaries of the organization (**B-P**).

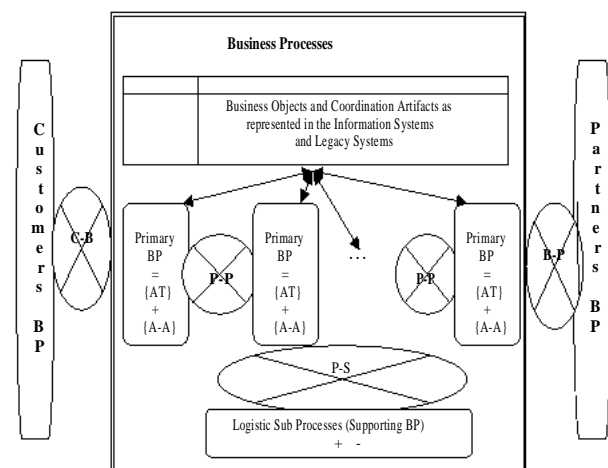

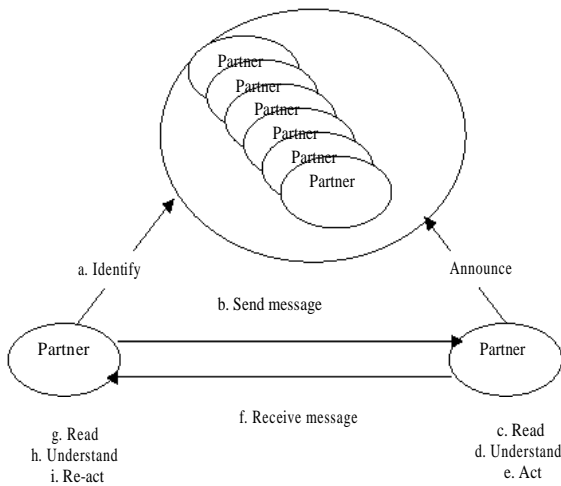

Fig. 1. Categories of Business Interactions

## 2.3 Interactions Common Activities

Regardless of their characteristics, i.e. dynamics, time, space, situations and categories, interactions require announced partners to perform the following activities as shown in Figure 2: (a) Identify the partner, (b) Send a message to the partner, (c) Read and interpret the message, (d) Understand the message, (e) Act

according to the interpretation and understanding (semantics required), (f) Receive a message, (g) Read and interpret the message, (h) Understand the message, and (i) Re-act according to the interpretation and understanding (semantics required).

**Fig. 2. Interactions Common Activities**

### 3. TECHNICAL ARCHITECTURE VIEW

The technical architecture view (Fig. 3) aims mainly at specifying the whole business IT system as a set of connecting IT subsystems that support business processes. The IT subsystems may be any combination of information systems, legacy systems and other kinds of applications. The interacting IT subsystems are:

1. Local subsystems that are different enterprise information systems (EIS) and legacy systems (LS) used to sustain primary and supporting business processes.
2. Clients subsystems that interact with local IT subsystems, these are stand-alone clients (SC: clients that interact through standalone applications), Web browsers (BC: clients that interact through browsers) and mobile clients (MC: clients that interact through mobiles).
3. Partners subsystems that interact with local IT subsystems, these are the partners information systems, legacy systems, components, objects or services.

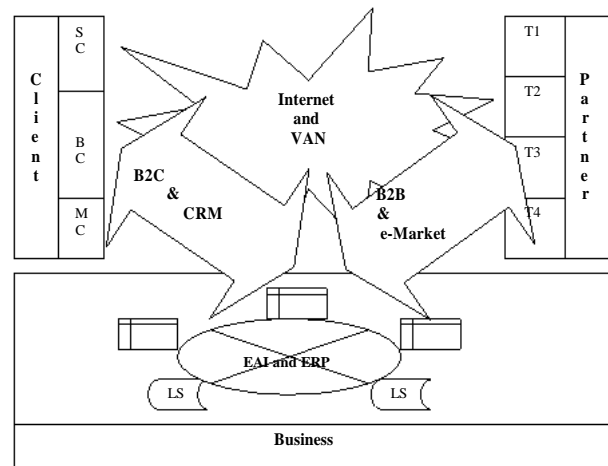

The connecting IT subsystems are interfaced and viewed as endpoints. That is, their internal behavior is encapsulated as a set of endpoints. The interfaces depend on the types of IT subsystems. That is, legacy systems and to a less extent enterprise information systems or applications will be wrapped to expose public interface. While, the components, objects and services are, by essence, specified as interfaces and implementations. The interfaces are:

1. Interfaces of the IT subsystems that are implemented with enterprise applications integration (EAI)

according to the integration orientation (data, applications or business processes) and different types of middleware (transactional, remote procedure call, messaging, message brokers, distributed objects computing, or SOAP).

2. Interfaces of the partners IT subsystems that are implemented through B2B electronic commerce applications (e.g. EDI, ebXML, Web services) or e-market brokers.

3. Interfaces of the clients that are implemented through B2C and CRM applications.

**Fig. 3. Technical View of Business Interactions**

This connection-oriented technical architecture view represents different categories of business interactions. To effectively allow dynamic business transaction, the implementing technology must emphasize connection of transparent and self-contained existing enterprise assets that don't tightly depend on each other. That is, a technology that allows loose coupling of the interacting elements. Web services technology is the *de facto* connections technology when deployed with respect to SOA architecture.

### 4. IMPLEMENTATION WITH WEB SERVICES

The technical architecture view is implemented with different technologies. Indeed, business interactions have been implemented as EAI, ERP, B2C, CRM, and B2B using traditional middleware, and distributed object-computing middleware (e.g. CORBA, DCOM and RMI) before the advent of SOA architecture and its instances, namely e-services and Web services. SOA architecture with Web services technology, despite the lack of maturity of the underlying standards, presents advantages with regard to (1) loose coupling of interacting elements, (2) dynamics, and especially (3) the connection-oriented applications of Web services.

#### 4.1 SOA Architecture

SOA architecture was first described by Gartner Group in 1996 as architecture based on the concept of service. It is essentially a collection of services that communicate with each other [2]. There exist several definitions of the term service. For instances, a kind of business oriented definition is given by [10] who defines a service as “business function of an application, so that another application or an application at another enterprise may find it useful to invoke”. A more technical definition is given by [13] who defines a service as “a location-transparent, network-addressable, invocable unit of software logic that is well defined, self-contained, and does not dependent on the context or state of other services”.

We consider a service as a self-contained element of the information system that implements business logic, business rule, or data operation (insert, update, delete, or retrieve data); and provided with a well-defined and standardized interface to be transparently accessible. This element of the information system must be designed and deployed with respect to SOA architecture. SOA aims mainly at achieving communication among loose coupling interacting software agents [8]. Therefore, Web services technology is the most attractive due to its underlying standards that enable communication between services within and outside the enterprise through a public network that is Internet.

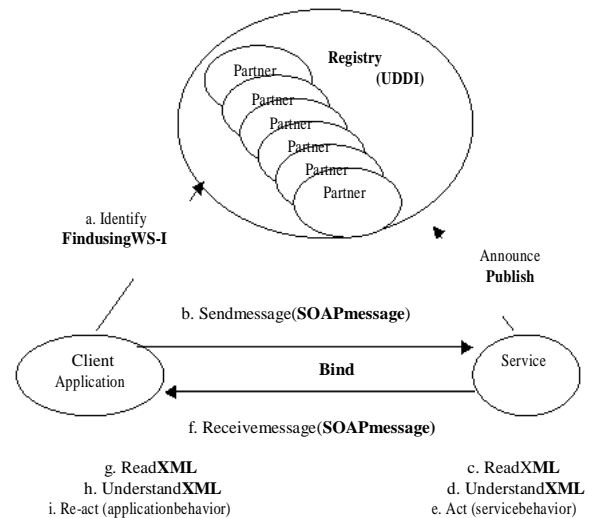

#### 4.2 Web Services as Internet Instance of SOA

W3C/WS Architecture Group defines Web services as “software system identified by URI, whose public interface and bindings are defined and described using XML. Other software can discover its definition. These software may then interact in a manner described by its definition using XML-based messages conveyed by Internet protocols” [1].

Web services technology is mainly a collection of technologies and standards that allow connecting services over the Web. These technologies and standards allow interfacing, publishing, binding, composing services through communications protocols based on Internet protocols (e.g. HTTP, SMTP, MIME). The standards XML, WSDL, UDDI, WS-I, BPEL, and SOAP allow communication and execution via the Web of self-contained and loosely coupled services within and outside the enterprise, which makes Web services technology not only the de facto integration standard, but also the de facto Internet standard instance of SOA architecture [14]. Web services technology can easily live with other technologies such as CORBA, DCOM, or RMI. These features of Web services will enable all the categories of business interactions as shown in the next section.

#### 4.3 Web Services Enabler of Business Interactions

The above interactions common activities can be easily implemented by the standards and technologies underlying Web services. Figure 4 shows how Web services stack and technologies (bolded in the figure) implement the interaction common activities.

**Fig. 4. Web Services and Common Activities**

#### 4.4 Web Services Enabler of EAI, B2B, CRM, B2C, and Dynamic e-Business

The features of Web services technology, notably their communication features enable all the categories of business interactions as summarized in Table 1.

##### 4.4.1 Web Services Enabler of EAI

EAI is an integration technology. It consists of providing interface to technologies implementing heterogeneous enterprise information systems and legacy systems. It aims at making applications composite to rapidly respond to business events, and to adapt to change in business conditions. The main features of EAI are:

- Connection of the applications (in different enterprise information systems and legacy systems).
- Introspection to look up and find applications or databases in order to connect them.
- Translation of data and messages exchanged between the applications and databases of the connected systems
- Control of flow of the applications, from within the different connected systems, involved in the composition of business processes.

These features can easily be enhanced with Web services technology. Indeed, Web services technology present transparent view of business logic, rules and data by interfacing and publishing them to be accessed, invoked, and consumed by applications that enter in the composition of primary and supporting business process.

EAI will easily support Web services. Indeed, Web

services are just a step in the evolution of technology and standards. The standards underlying Web services will ultimately simplify application integration within and outside organizational boundaries. These standards (when matured enough) will allow Web services to become the de facto integration standard by supporting all features of EAI. Moreover, Web services reduce the complexity and the cost of the traditional integration middleware.

#### 4.4.2 Web Services Enabler of B2B

A B2B application consists of connecting applications from different businesses to exchange agreed upon (or standardized) business documents (e.g. order, invoice). For large organizations, this has been achieved based on EDI specifications. Despite the evolution of EDI, from EDI data transmission, VAN (used to simplify complexity of multiple connections), DCOM and CORBA (used to reduce the cost related to VAN and to standardize the message), to XML as EDI standards, there are still challenges that can be addressed by XML and Web services. Indeed, Web services (with matured underlying technologies and standards) are used in B2B to:

- Reduce the cost of entry into B2B for small and medium businesses. Indeed, EDI deployment and maintenance is very costly, which deprives small and to a less extent medium businesses to play the right role they are intended to in the economics arena.
- Allow effective dynamics. Indeed, EDI specifications assume a long term fixed and well-specified interactions (e.g. agreed upon format) deployed through proprietary networks. Web services connecting technology is based on the contract of type "take or leave", which gives more freedom and dynamics to businesses to choose transparent services accessed through the protocols of the Internet (a public network).
- Fix the problem of the difference in semantics, and the problem of fixed record format of exchanged between businesses applications as imposed by EDI specifications.

#### 4.4.3 Web Services Enabler of CRM

CRM system is an information system that records information such as customer contact information. A CRM system is generally used by customers and representatives. A CRM system is not necessary an internal system. On the contrary, external CRM systems are better suited to be accessed as Web services. Indeed, CRM as Web services will certainly present better services, performance and reliability.

#### 4.4.4 Web Services Enabler of B2C

Web services will facilitate the development and deployment of applications that can be readily accessed by PDA, office devices, and mobile devices in addition

to Web browsers. Web services will permit applications developers to better leveraging existing businesses logic, rules and data by invoking them by any kind of clients. Moreover, Web services will reduce search complexity for exiting services.

#### 4.4.5 Web Services Add-Value

Web services features add value to traditional applications used to implement internal and external business interactions as summarized in Table 1.

**Table 1. Value added by Web services**

<b>Interactions Applications</b>	<b>Value added by Web Services Technology</b>
EAI	<ul style="list-style-type: none"> <li>• Standardized interfaces of the elements of the enterprise information systems and legacy systems.</li> <li>• Connection of loosely coupled elements of the enterprise information systems and legacy systems.</li> <li>• Introspections through UDDI and WSDL.</li> <li>• Use of XML to exchange and translate messages.</li> <li>• Control of the flow of the integrated applications through BPEL.</li> </ul>
B2B	<ul style="list-style-type: none"> <li>• Entry into B2B to small and medium enterprise (VAN is no longer required).</li> <li>• Dynamic business interactions. Businesses are really autonomous in their interactions</li> <li>• Free message format using XML. Messages format not fixed and standardized.</li> </ul>
CRM	<ul style="list-style-type: none"> <li>• Use of external as well as internal CRM applications accessible from anywhere through Internet.</li> </ul>
B2C	<ul style="list-style-type: none"> <li>• Applications involved in B2C are better interfaced (WSDL) to be accessible through different means, i.e. office devices, PDA and mobile devices in addition to Web browsers.</li> <li>• Search and tracking facilities exposed as Web services.</li> </ul>
Dynamic e-Business	<ul style="list-style-type: none"> <li>• Dynamic binding facility allows business applications or services to bind to services at run-time.</li> <li>• UDDI and WS-I allows inspection and selection of efficient services and cost-effective connection.</li> </ul>

## 5. RELATED WORK

Business interactions have been implicitly seen as an integration problem with an IT perspective rather than a business perspective. That is, the issue is often how to make information systems (including applications and databases), running on different platforms, interoperable to exchange structured as well as unstructured data? Various integration ways have been approached, namely: (1) a data-oriented integration (e.g. distributed databases [3]), (2) an object-oriented integration based on distributed object computing middleware (e.g. COBRA, DCOM, RMI), and (3) a

service-oriented integration based on SOAP middleware (e.g. e-services, Web service).

The object-oriented integration approach makes applications interoperable through a broker used for discovery and invocation. In this category, CORBA, DCOM and RMI were designed mostly from an IT perspective in order to help developers operate more effectively [15]. Due to their great returns and quality productivity, these technologies have been used in EAI, and B2B to offset the complexity related to value added networks (VAN) used as brokers in EDI. However, they do not allow a loose coupling because they are built on their own technology.

In the last years, clear trend is to move away from data-oriented and object-oriented integration to service-oriented integration [2][5][7][8][9][15].

The state of art shows SOA and Web services with praise. This technology is now widely adopted because it allows connecting partners (e.g. B2B integration) with reduced cost [4]. The ultimate goal of this technology is to enable dynamic e-business. Web services technology is a main focus of various software development companies [6]. It is considered as the hottest topic by software industry.

Our approach presents a model of business interactions as a framework that allows guidance towards a method to deploy Web services as add value for the exiting applications that are EAI, B2C, CRM, and B2B. The framework is used to abstract and then deploy a comprehensive and multipurpose set of services with respect to SOA. A model of business interactions simplifies the vision and the technological architecture.

## 6. CONCLUSION

We have proposed a framework for business interactions, as one of the most important perspectives of a business modeling besides the business processes, business objects and business events perspective. An interactions perspective is critical while deciding the alignment and deployment of an enabling connecting technology. This abstraction is made up of three architectural views of business interactions: conceptual, technical, and Web services.

The main goal of the business interactions abstraction is to propose recommendations and guidance that help generating, and deploying a set of Web services with respect to SAO architecture. The abstraction makes clear the breakups of the business processes and the technological requirements to fill these breakups.

We have shown how the features of Web services technology as Internet instance of SOA architecture add value to the features of EAI, B2C, CRM, B2B in order to ultimately allow dynamic e-business.

Deploying Web services technology with respect to architecture is a critical issue nowadays where businesses need to cost-effectively and dynamically integrate business processes that cross their boundaries, which is critical for their survival.

This work can be extended by developing models and supporting tools towards a method for deploying Web services as an Internet standard instance of SOA.

### ABSTRACT

This paper focuses on demand chain management, which accomplishes the synchronization of demand with supply through collaboration of buyer and supplier across the chain. And the purpose of it is to find the relationship between four integration strategies produced by combining supply integration and demand integration and its impacts on two performances, operating efficiency and customer satisfaction. The relationship is analyzed with respect to manufacturing and services respectively. Interestingly, our results show that the strength of integration affects differently two performances.

**Keywords:** Supply chain; Web-based Integration Strategy; Demand integration; Supply integration; Efficiency; Customer satisfaction

### 1. INTRODUCTION

A supply chain is composed of components involved in designed to produce products and services, procuring raw materials, transforming them into semifinished and finished products, and delivering them to end customer. In contrast, demand chain management (DCM) is defined a practice that manages and coordinates the whole supply chain, starting from the end customer and working backwards to raw material suppliers (Vollmann et al., 2000). For more specific, DCM is focusing on synchronizing demand with supply through customer and partner collaboration across multiple channels, while supply chain management (SCM) is managing and optimizing the sourcing, production and distribution operations of the enterprise to match a given demand (Woods, 2002).

Why Demand Chain Management is important? It is because three market dynamics are increasing the complexity and criticality of intelligently executing upon supply and demand chain processes: increased demand volatility, accelerating product changes and highly distributes supply. It is virtually impossible to 100% accurately forecast demand. Today the volatility of market demand for most products has increased. The costs of inaccurate forecasts have increased due to smaller profit margins, more rapid product price drops, and shorter product lifecycles. Demand volatility has also increased due to the expansion of distribution and sales channels. Companies continue to innovative and develop more advanced and sophisticated products that serve consumers' and businesses' appetite for technology and its uses. The supply-side network for many manufacturing companies has experienced fundamental changes. Companies have increased their manufacturing outsourcing and have become more reliant upon a broader network of component and customer suppliers.

Demand volatility, product innovation and distributed supply networks are creating new business challenges for manufacturing companies and their supply and demand chain partners. Information latency and lack of visibility across this chain of partners result in a situation where the manufacturing companies can not effectively manage the new market volatility.

To be efficient and contribute to high customer satisfaction is one of important challenges in manufacturers and services. Through e-business, it is possible to serve customers individually with customized bundles of goods and services. However, it is difficult to improve both operational efficiency and customer satisfaction. Implementing a rigid approach in management would lose customer satisfaction. On the other hand, getting customization would decrease efficiency. For a supply chain, demand-side companies enhance high customer satisfaction composed of fill rate, customer's perception of the service from them, etc., whilst supply-side ones try to increase operational efficiency composed of lead-time, inventory level, inventory turnover, etc.

In order to achieve higher operational efficiency and customer satisfaction, DCM should be extensive up- and downstream integration between companies involved in the chain. Throughout the Internet, the integration has only become possible nowadays. And the tradeoffs between low cost, speedy transaction, diverse service, broad networks and rich content across the chain are resolved effectively through the web.

To be successful implementation of DCM, it is necessary that DCM has three components: Integrate, Exchange and Synchronize (Woods, 2002). Firstly, Integrate is performing data integration over the chain; secondly, Exchange is enabling collaboration with trading partners

to share intellectual capital about demand. Finally, Synchronize is creating business processes, not just data synchronization, that integrates knowledge about the chain performances to shape demand in this extended value network. Also, web-based technologies are increasingly indispensable for not only exchange and integration but also knowledge synchronizing.

Korea firms are mostly on the level of high position in infrastructure of the Internet. But it is not for e-business or business process. It correctly says that they are now struggling in integration of the Web with their business processes. So we sampled the companies posted in higher level on e-business processes.

By using supply-side or demand-side integration across the chain, demand and supply integration strategies address four strategic alternatives (Frohlich and Westbrook, 2002). They are shown in Fig. 1. Whilst model A indicates a strategy of little or no web-based integration of both sides, model D is oppositely a strategy with high levels of web-based integration collaborating with both sides partners. In between the other dimensions are strategies with supply-side integration of companies (model B) and demand-side integrations (model C). Adopting a web-based integration strategy requires collaborative agreements of problems on sharing information, benefit, knowledge of industry and market, etc. with suppliers and customers. Throughout the agreements, a company could decide a long-term plan for implementing strategies. To generate the plan effectively, a company should investigate how much the performances, operational efficiency or customer satisfaction, are increased through adoption of each strategy.

The objective of our study is to find the relationship between adopting web-based integration strategy and its impacts on two performances with manufacturing and services in Korea. For more specific, this research investigates whether there is a difference between the impacts of each selected strategy on two performances: operational efficiency and customer satisfaction, and also a difference between the impacts in manufactures and services.

## 2. LITERATURE REVIEW

Substantial previous research highlights many opportunities separately associated with either supply and demand integration in supply chain (Table 1). As Handfield (1993) mentioned, supply integration means "obtaining frequent deliveries in small lots, using single or dual sources of supply, evaluating alternative sources on the basis of quality and delivery instead of price, establishing long term contracts with suppliers, reducing buffer inventories and eliminating formal paperwork." The supply integration does not only reduce costs but also improve lead times. Through the Internet, other benefits include improved supplier reliability (Carr and

Peason, 1999) and communication (Freeland, 1991).

In terms of the demand-side of companies, major challenges are improving demand visibility and planning in supply chains (Fisher et al., 1994). As Lee et al. (1997) noted, distorted demand information in a supply chain would incur tremendous inefficiencies: excess inventories, poor customer service, lost profits, misguided capacity plans, ineffective transportation and missed production schedules. One trend is integrating up- and downstream information to coordinate non-vertically integrated firms (Marbert and Venkataramanan, 1998). Due to magnification of unstable planning over supply chains, it needs controlling this amplification, which is essential to good demand management. Information technologies involving the web would make the demand integration successfully, which could include shared data between planning and control systems (Bowersox and Daugherty, 1995).

In demand chains, other interested issues are improving delivery efficiently and rapidly (Bhatnagar and Viswanathan, 2000; Cachon and Fisher, 2001; Heikkila, 2002) and logistics communication (Corbett et al., 1999). Basics of the core of demand-driven supply chain integration strategy are demand forecast integration, inventory reductions and the elimination of non-valued added activities.

E-business— the use of Internet-based computing and communications to execute both front-end and back-end business processes — has emerged as a key enabler to drive supply chain integration (Lee and Whang, 2001). The Internet creates a new environment for exchanging information and conducting business transactions. The most direct effect of the Internet is to create new opportunities to improve the efficiency and effectiveness of the operation of the supply chain. This is because of the cost-effective capacity to generate visibility across all aspects of the supply chain, including point-of-sale information, manufacturing schedules, vendor stocks, customer inventories, demand patterns, sales/marketing initiatives, and carrier schedules.

And the Internet is an enabler to actually combine customers and suppliers over a supply chain. Pre-internet, real-time demand information and inventory visibility were almost impossible to achieve and most supply and demand integration involved a patchwork of telephoning, faxing, and EDI. Web-based technologies allow customers and suppliers to co-operate each other for inventory planning, demand forecasting, order scheduling, target marketing, and customer relationship management. And the greatest potential of the Internet is being realized by speeding up communication between customers and their suppliers, improving service levels, and reducing logistics costs (Lancioni et al., 2000). Lee and Whang (2001) have offered a view emphasizing e-business applications to the supply chain: planning and

execution of the front-end and back-end operations in a supply chain using the Internet.

Throughout the Internet, traditional demand and supply integration practices present four strategic alternatives (Frohlich and Westbrook, 2002). The worst is a strategy of little or no web-based integration (model A). Next, two models are introduced groups whose strategies involve web-based integration with either their suppliers (model B) or customers (model C). And last is a strategy with high levels of web-based integration, which requires being cooperative among the whole demand chain members from customers backwards to suppliers called DCM (model D). Frohlich and Westbrook(2002) suggests that the higher the level of integration intensity with suppliers and customers, the greater the benefits. Our study involves above four strategies.

Through the Web, firms are able to obtain global visibility across their extended network of trading partners and respond rapidly to diverse customer demand. Applying the Web into their demand chain makes them more beneficial to efficiency in internal view and customer satisfaction in external view.

Web-based DCM strategy performs the highest operational efficiencies; faster delivery time, reduced transaction costs, greater profitability and enhanced inventory turnover (Frohlich and Westbrook, 2002). And customer satisfaction is composed of higher fill rate, customer loyalty, recommendations, and enhancing customer's perception on pricing and the quality of a product. Heikkila (2002) studied on a demand chain of mobile telecommunication technology capable of increasing operational efficiency and customer satisfaction. In the chain, high customer satisfaction is more important rather than efficiency. The problem of focusing one of both would depend on a company's situation: type of its role as a component in the chain, type of a product, etc.

To high operational efficiency or customer satisfaction, DCM is required extensive up- and downstream integration between companies involved in the chain. Throughout the web, the integration could be very speedy, and also, it can effectively resolve the tradeoffs between low cost, speedy transaction, diverse service, broad networks and rich content across the chain.

### 3. RESEARCH METHOD

#### 3.1 Research model and hypotheses

As Narasimhan and Jayaram (1998) studied, a low integration strategy (model A) in the Internet era should deliver the fewest benefits among four integration strategies. The DCM strategy (model D) should deliver the highest levels of performance. The higher the level of traditional integration with suppliers and customers the greater the benefits, as Frohlich and Westbrook (2001)

noted, and the Internet should only reinforce this relationship. The performance for the supply integration (model B) and the demand integration (model C) strategies should logically fall between the low integration (model A) and DCM (model D) approaches. Fig. 1 shows the research model and study hypotheses.

The following arguments lead to the set of hypotheses.

H1a. Manufacturers and services adopting a web-based DCM integration strategy (model D) will have the highest levels of operational efficiency.

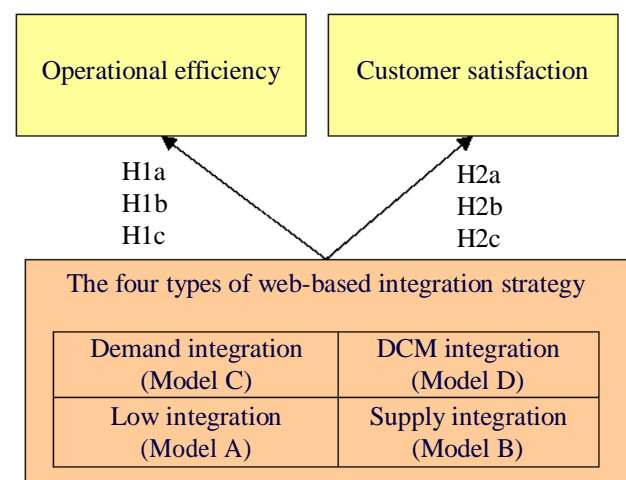

H1b. Manufacturers and services adopting a web-based supply (model B) or demand (model C) integration strategy will have medium levels of operational efficiency.

H1c. Manufacturers and services adopting a low web-based integration strategy (model A) will have the lowest levels of operational efficiency.

H2a. Manufacturers and services adopting a web-based DCM integration strategy (model D) will have the highest levels of customer satisfaction.

H2b. Manufacturers and services adopting a web-based supply (model B) or demand (model C) integration strategy will have medium levels of customer satisfaction.

H2c. Manufacturers and services adopting a low web-based integration strategy (model A) will have the

lowest levels of customer satisfaction.

Fig. 1. Research model and hypotheses

#### 3.2 Operational definitions and measure items of variable

Some factors mentioned in this research are extracted through existing studies of Table 1. The others, especially related to customer satisfaction factor, are through the relevance of demand chain factor. Operational definitions, measure items of variable and sources of variables are described in Table 1.

As it mentioned in Section 2, it generates four integration strategies by using the two types of integration. While the factor of operational efficiency describes company's

performance: delivery time, transaction cost, profitability, and inventory turnover, through the web-based integration, the factor of customer satisfaction shows customer's perceptions for a company: information support for products and services, intent to continuous

transaction, satisfaction of price, quality and delivery, and likelihood to recommend supplier to other customers. The scale for all measure items depicted in Table 1 is a 7-point Likert scale with 1 indicating not agreed at all, 4 indicating so-so and 7 indicating fully agreed.

Table 1. Operational definitions and measure items of variable

Factor	Operational definition	Measure item	Studies
Supply integration	Levels of web-based supply chain integration with suppliers	Integrated inventory planning with suppliers	Frohlich and Westbrook(2001), Lancioni et al. (2000), Lee and Whang(2001), Rahman(2003)
		Integrated supply chain management with suppliers	Frohlich and Westbrook(2001), Lancioni et al.(2000), Lee and Whang(2001), Rahman(2003)
		Integrated demand forecasting with suppliers	Frohlich and Westbrook(2001), Lancioni et al. (2000), Lee and Whang(2001), Rahman(2003)
		Integrated order scheduling and tracking with supplier	Frohlich and Westbrook(2001), Lancioni et al. (2000), Lee and Whang(2001), Rahman(2003)
Demand integration	Levels of web-based supply chain integration with customers	Targeted marketing/customer profiling	Heikkila(2002)
		Online order taking/receipt	Lee and Whang(2001)
		Integrated demand forecasting with customers	Frohlich and Westbrook(2001), Heikkila(2002), Lancioni et al.(2000), Lee and Whang(2001), Rahman(2003)
		Customer relationship management	Heikkila(2002), Lee and Whang(2001)
Operational efficiency	Levels of achievement by web-based integration with suppliers or/and customers	Faster delivery time	Frohlich and Westbrook(2001), Heikkila(2002), Lancioni et al. (2000), Lee and Whang(2001), Rahman(2003)
		Reduced transaction costs	Lancioni et al. (2000), Lee and Whang(2001)
		Improved greater profitability	Chien et al.(2003), Frohlich and Westbrook(2001), Lee and Whang(2001)
		Enhanced inventory turnover	Frohlich and Westbrook(2001), Heikkila(2002), Lancioni et al. (2000), Lee and Whang(2001)
Customer satisfaction	Levels of satisfaction for purchasing producer's products or services	Information support for products/services	Chien et al.(2003), Frohlich and Westbrook(2001), Heikkila(2002), Lee and Whang(2001), Lancioni et al. (2000)
		Intending to continuous transaction (customer royalty)	Chien et al.(2003), Heikkila(2002)
		Satisfaction of price, quality and delivery	Chien et al.(2003), Frohlich and Westbrook(2001)
		Recommending producer to other customers	Chien et al.(2003)

### 3.3 Data collection

The survey was developed in three stages. In the first stage, we identified relevant measures of web-based demand and supply integration, operational efficiency, and customer satisfaction in the literature and drafted the instrument. In the second stage, we pre-tested the survey with 90 manufacturers and service firms to further gauge its content validity and overall readability. In the final stage, we executed the survey.

Data were collected from random samples of manufacturing and services from across Korea. Questionnaires were divided of two types. One is for company; the other is for his customer. We sampled from 7 regions of Korea including Seoul and Busan and, in the external validity, the companies sampled in Korea do

well in e-business and the infrastructure of the Internet of Korea is ranked higher. 640 questionnaires are sent to company of manufacturing or services, and his customer by e-mail for convenience. And company's respondents were mostly managers with enough seniority to know about their companies'up- and downstream integration, and operational efficiency. Customers responded the level of customer satisfaction about his supplier. In our study, to gather more accurate response with consideration of Korean characteristic, all of variables in Table 2 were measured by a 7-point Likert scale: 7 = fully agreed, 4 = middle, and 1 = not at all. Returned usable questionnaires were totally 209 and the survey response rate was 32.7%. Responses of company are 118 cases; 40 manufacturers, and 78 services. And responses of customer are 91; 29 manufacturers and 62 services.

#### 4. HYPOTHESES TEST AND RESULTS

This study analyzed the differences, concerning relationships between web-based integration strategies and performance in manufacturing and services, using ANOVA and the Scheffé method. Table 2 shows the results. In the table, demand chain integration strategy (model D) was archived the highest performance, and then demand integration strategy (model C) and supply integration strategy (model B) were next. Low integration strategy (model A) was the lowest.

And in Table 2, the manufacturers that employed demand chain integration strategy (model D) have archived the highest operational efficiency than the other strategies. While there is significant in between adopting model C

and model D, they were not significantly different from other strategies. The manufacturers with model B had higher operational efficiency than model A and lower operational efficiency than model D. In services, model B, model C and model D had not been significantly different each other, but they were significantly different from model A. Using the results of ANOVA, we tested the set of hypotheses. Table 3 represents the results for hypothesis test by manufacturers and services. As a further evaluation of H1a, H1b and H1c for operational efficiency, and H2a, H2b and H2c for customer satisfaction, the total of manufacturers and services were merged together and regression was run to test effect of web-based integration (models A-D) on performance for operational efficiency and customer satisfaction separately.

Table 2. ANOVA for performance by integration strategy and company type

Cluster	Manufacturers <sup>a</sup>						Services <sup>a</sup>						Total <sup>a</sup>					
	Operational efficiency			Customer satisfaction			Operational efficiency			Customer satisfaction			Operational efficiency			Customer satisfaction		
	m	s	n	m	s	n	m	s	n	m	s	n	m	s	n	m	s	n

a. m: mean; s: standard deviation; n: number of cases; alphabets in parentheses show which other integration strategy type the cluster's means performance is significant different from.

\*: P < 0.10, \*\*: P < 0.05, and \*\*\*: P < 0.01 significance.

Table 3. Results of hypothesis test

	Hypothesis	Decision
H1a	Manufacturers adopting a web-based DCM integration strategy (model D) will have the highest levels of operational efficiency.	Supported
	Services adopting a web-based DCM integration strategy (model D) will have the highest levels of operational efficiency.	Not supported
H1b	Manufacturers adopting a web-based supply (model B) or demand (model C) integration strategy will have medium levels of operational efficiency.	Partial supported (only Model B)
	Services adopting a web-based supply (model B) or demand (model C) integration strategy will have medium levels of operational efficiency.	Not supported
H1c	Manufacturers adopting a low web-based integration strategy (model A) will have the lowest levels of operational efficiency.	Partial supported
	Services adopting a low web-based integration strategy (model A) will have the lowest levels of operational efficiency.	Supported
H2a	Manufacturers adopting a web-based DCM integration strategy (model D) will have the highest levels of customer satisfaction.	Not supported
	Services adopting a web-based DCM integration strategy (model D) will have the highest levels of customer satisfaction.	Not supported
H2b	Manufacturers adopting a web-based supply (model B) or demand (model C) integration strategy will have medium levels of customer satisfaction.	Not supported
	Services adopting a web-based supply (model B) or demand (model C) integration strategy will have medium levels of customer satisfaction.	Not supported
H2c	Manufacturers adopting a low web-based integration strategy (model A) will have the lowest levels of customer satisfaction.	Not supported
	Services adopting a low web-based integration strategy (model A) will have the lowest levels of customer satisfaction.	Not supported

## 5. CONCLUDING REMARKS

About impacts of four strategies on two performances, it is not significant at level of 95% that there are differences of the impacts on customer satisfaction by four strategies regardless of industry, while it is significant in the difference of the impacts on efficiency by manufacturers and services. Through the mean values on performance of efficiency, the model D, for manufacturing companies, shows the highest value and next orders are B, C, and A. The result means that a manufacturing company focuses on supply integration of suppliers and thereby accomplishing the internal efficiency. In contrast, for services, the descending order of mean values is D, B, C and A, but there is no difference between B and C. This means that a service company focuses on demand integration of customer to enhance customer satisfaction rather than efficiency. And it is not common in services since some of them do not have the supply part. And an integrated company with supplier gains more efficiency than that with customer. In reverse, an integrated company with customer acquires higher customer satisfaction than that with supplier. Therefore, this research addresses important results as follows:

• Manufacturers and services to pursue operational efficiency or customer satisfaction are able to achieve the best performance model by adopting demand chain management integration among the integration strategies.

• Supply integration provides better performance for manufacturers than demand integration in pursuing operational efficiency or customer satisfaction.

• Supply integration provides better performance for services than demand integration in pursuing operational efficiency.

• Demand integration provides better performance for services than supply integration in pursuing customer satisfaction.

• A low integration delivers the fewest benefits to manufacturers and services.

### ABSTRACT

Recognizing the value of information sharing among supply chain partners, a growing number of firms have expressed keen interest in jointly creating customer demand, managing business functions and leveraging the strength of their supply chain partners. In particular, such interest sparked the rapid development and implementation of collaborative planning, forecasting and replenishment (CPFR) that was proven to be successful in minimizing safety stocks, improving order fill rates, increasing sales, and reducing customer response time. Despite increasing popularity, key drivers for the successful development and implementation of CPFR have not been fully understood by practitioners and academicians alike. This paper unveils the invisible challenges and opportunities for adopting and implementing CPFR. Also, it provides an overview of CPFR in comparison to other alternative forecasting techniques such as agent-based forecasting and focus forecasting, while synthesizing the past evolutions and future trends of CPFR in a supply chain setting.

**Key words:** Collaborative Planning, Forecasting and Replenishment, supply chain management, demand planning

### 1. INTRODUCTION

In contrast to the traditional business paradigm that focuses on the effectiveness and efficiency of separate business functions, a growing number of firms have begun to realize the strategic benefits of jointly planning, controlling, and designing a supply chain as a whole through inter-functional and inter-organizational integration. These benefits include: reduced inventory (or working capital), less frequent rush delivery, faster product flow, quicker customer response time, higher asset utilization, larger market share, and increased revenue and profit. Despite a host of benefits gained from supply chain integration, only a few firms have adopted and successfully implemented a concept of jointly planning, controlling, and designing a supply chain. In fact, Gustin (2001) reported that less than one third (26%) of the 300 U.S. companies surveyed recognized and successfully implemented supply chain integration. Also, the respondents of the American Shipper/Mercer Management Consulting Survey conducted by Artman and Sabath (1995) indicated that supply chain integration was one of the most pressing logistics related problems. A lack of success in implementing supply chain integration is often due to poorly coordinated data exchange or information sharing among supply chain partners. Thus, the ultimate success of supply chain integration will depend on supply chain partners' willingness to share real-time information throughout the supply chain and develop joint planning processes for adding value to end-customers' needs (see, e.g., Raghunathan, 1999; Cachon and Fisher, 2000; Lee et al., 2000; Thonemann, 2002; Zhao et al., 2002 a, b for various benefits of sharing information in supply chains). An information sharing process that has gained increased popularity

over the years is collaborative planning, forecasting, and replenishment (CPFR).

In general, CPFR is referred to as a nine-step joint demand planning process that aims to enhance supply chain visibility by improving order forecasts and fulfillment through continuous communications among multiple supply chain partners. The nine-step process is comprised of: (1) develop front-end agreement; (2) create joint business plan; (3) create sales forecasts; (4) identify exceptions for sales forecasts; (5) resolve/collaborate on exception items; (6) create order forecasts; (7) identify exceptions for order forecasts; (8) resolve/collaborate on exception items; (9) order generation (see, e.g., Ackerman, 2000; Logility, 2000). The detailed steps of CPFR are graphically displayed in Figure 1. Although CPFR evolved from traditional collaborative tools, such as: electronic data interchange (EDI), vendor managed inventory (VMI), and efficient consumer response (ECR), it differs from others in that it brings mutual benefits to all the supply chain partners involved by utilizing more interactive, broader communication processes throughout the supply chain rather than relying on limited transaction-level automation. Other benefits of CPFR include: higher inventory turnover, lower stock-out rate, improved order fill rate, improved cash flow; more accurate production scheduling, more amicable business relationships among supply chain partners, reduced cycle time, reduced order picking/receiving costs, reduced labor costs, and quicker response to customer needs (Sherman, 1998; Williams 1999; Barratt and Oliveira, 2001; Langabeer and Stoughton, 2001; McKaige, 2001; McCarthy and Golicic, 2002; Andraski and Haedicke, 2003). For example, the pilot implementation of CPFR by Wal-Mart and its supplier, Warner-Lambert,

increased average in-stock rates from 87 to 98%, reduced lead time from 21 to 11 days, and increased sales volume by \$8.5 million in 1995 (Fahrenwald et al, 2001). A German office supplies manufacturer named Herlitz AG, which shared information with its retailer named Metro through CPFR, reduced its inventory by 15%, curtailed its stock-outs by 50%, and increased its annual sales by 3% (Andraski, 2000). Similarly, Johnson & Johnson reported to increase its in-stock rate from 91.5% to 93.8% after adopting CPFR (Inventory Management Report, 2002). After CPFR was implemented for Sears and Michelin in 2001, they reported that in-stock levels at the Sears stores were improved by 4.3% and Sears distribution centers-to-store fill rate was increased by 10.7%, while the combined Sears and Michelin inventory levels were reduced by 25% (Steermann, 2003). The detailed illustration of CRPF implementation success for other companies can be found in Seifert (2003).

Despite the aforementioned promises, CPFR is not without its obstacles. These obstacles may include: cultural and technical incompatibility among supply chain partners, lack of trust among supply chain partners, lack of scalability, lack of internal alignment, inadequate software and technology support, substantial start-up investment for building a communication infrastructure, antitrust laws, legacy systems, and difficulty in real-time coordination of information exchange (e.g., Mentzer et al., 2000; Barratt and Oliveira, 2001; McCarthy and Golcic, 2002; Seifert, 2003). One way of overcoming such obstacles is the integration of CPFR with other alternative forecasting tools, such as: agent-based forecasting and focus forecasting, that can complement CPFR. With this in mind, the primary purposes of this article are to:

1. Compare and contrast CPFR with other related demand forecasting and planning techniques such as agent-based forecasting and focus forecasting;
2. Synthesize the existing CPFR literature with respect to their practical implications and technical merits;
3. Develop a hierarchical taxonomy for the existing CPFR literature and categorize it according to its application area, problem scope, and methodology;
4. Summarize research trends and identify untapped research topics associated with CPFR;
5. Discuss the future outlook for extensions of existing CPFR literature.

## 2. CPFR VS. AGENT-BASED FORECASTING

Since a supply chain involves the synchronization of a series of inter-related but different stages of business processes influencing multiple trading partners, its demand planning and forecasting cannot rely on a single, stand-alone forecasting tool. One of the emerging concepts that fits into the supply chain framework is agent-based forecasting which was designed to

automate the coordinated planning and communication processes throughout the entire supply chain. In general, agent-based forecasting is a computer-based forecasting system that aims to facilitate enterprise-wide integration through non-proprietary message transfers and automated reasoning capabilities available from intelligent software agents. According to Reis (1999), an agent refers to an autonomous entity that can take certain actions to accomplish a set of goals and can compete and cooperate with other agents while pursuing its individual goals. An agent is often characterized by its ability to exploit significant amounts of domain knowledge, overcome erroneous input, use symbols and abstractions, learn from the environment, operate in real time, and communicate with others in natural language (Newell, 1989).

Exploiting such characteristics, an agent concept was recently introduced to handle various logistics and supply chain issues including a shop floor control within a material requirement planning (MRP), traffic control, joint production planning, and business-to-business communication and negotiation (Van Dyke Parunak, 1988; Satapathy et al., 1998; Swaminathan, 1998; Garcia-Flores et al., 2000; Fox et al., 2000; Ito and Saleh, 2000). More recently, Yu et al. (2002) developed an agent-based forecasting system to predict end-customer demand through information exchange among supply chain partners. In forecasting applications, they utilized four multiple agents with different roles: task agents; coordination agents; data collection agents; interface agents (see Figure 2 for a graphical display of these agents). Their experiments with actual data showed that agent-based forecasting performed better to predict end-customer demand than a collection of traditional time series forecasting techniques in a supply chain setting. Thus, they conclude that agent-based forecasting was suitable for demand planning in a supply chain setting as a substitute for CPFR. Though CPFR and agent-based forecasting have similarities in that both are intended to coordinate multiple sources of data for joint demand planning and forecasting, they differ in many respects. The differences between CPFR and agent-based forecasting are summarized in Table 1.

## 3. CPFR VS. FOCUSED FORECASTING

Focus forecasting is an expert system that identifies a simple forecasting rule-of-thumb, which worked best in the past, and uses it to make a short-term prediction for future events such as sales or customer demands. Focus forecasting is often comprised of three steps: (1) simulate the past forecasts using a variety of simple forecasting rules; (2) evaluate the performances of these simple rules with respect to forecasting errors such as mean absolute deviation (MAD) and mean absolute percentage error (MAPE); (3) select the forecasting rule that performed best as the forecasting method that will be used to forecast the next period's demand. Also, focus

forecasting is characterized by its simplicity, lack of file maintenance, and user friendliness (Smith, 1991; Smith, 1997). Focus forecasting is different from CPFR in that the former does not involve trading partners for making forecasts and focuses on internal forecasts within the company, whereas the latter shares information with the multiple supply chain partners and develop both intra- and inter-organizational demand plans (see Table 1 for detailed distinctions between CPFR and focus forecasting).

#### 4. TAXONOMY OF THE CPFR LITERATURE

The CPFR taxonomy to be developed here uses three broad classification schemes: (1) *problem scope* as a criterion for measuring the breadth and depth of the CPFR study, (2) the *methodology* as a criterion for evaluating the theoretical advance of the CPFR study, and (3) the *implementation status* for assessing the practicality of the CPFR study.

##### 4.1 Problem scope

The problem scope is categorized with respect to the level of CPFR integration: (1) *intra-organizational integration* across different business functions; (2) *inter-organizational integration* across vertical supply chain links. The inter-organizational integration can be further sub-classified into: (1) *two-tier* integration; (2) *n-tier* integration. A two-tier integration focuses on the collaborative relationship between two primary supply chain partners (typically the manufacturer and retailer); whereas, a n-tier integration involves more than two (multiple) supply chain partners across the industry and vertically extends information sharing mechanism to minimize “bullwhip” effects as illustrated in Figure 3. The bullwhip effect is generally referred to as an inverse ripple effect of forecast errors throughout the supply chain that often leads to amplified supply and demand misalignment where orders to the upstream supply chain partner tend to exaggerate the true patterns of end-customer demand since each supply chain partner’s view of true demand can be blocked by its immediate downstream supply chain partners (see, e.g., Lee et al. 1997; Min, 2000). Either two-tier or n-tier integration can also be subdivided into one-to-one, one-to-many, and many-to-many integration (e.g., CPFR partnerships among multiple manufacturers and multiple retailers) depending on the number of horizontal supply chain partners involved in CPFR.

##### 4.2 Methodology

The broad subcategories of methodological classification are descriptive (conceptual) and normative (analytical) studies. The descriptive studies often illustrate the numerous managerial benefits of using CPFR or evaluate the outcomes of CPFR in comparison to traditional stand-alone demand planning through case examples. On the other hand, normative studies

designed quantitative models to assess the positive impact of CPFR (or information sharing across the vertical supply chain) on various supply chain performances in comparison to old legacy systems or less structured forecasting procedures. These quantitative models can be broken down into mathematical models and simulation experiments. The core mathematical models also include various forecasting techniques which may be categorized as: time series and causal methods. Time series (univariate forecasting) methods assume that the past is an adequate representation of the future and that a product’s past demand pattern can be extrapolated to predict future demand (Tyagi, 2002). Causal (multivariate forecasting) methods make predictions of the future by modeling the relationship between a series and other series (DeLurgio, 1998). Time series methods include moving average, exponential smoothing, decomposition, linear trends, and Box-Jenkins, while causal methods include regression and econometric models (Chambers et al., 1971; DeLurgio, 1998).

##### 4.3 Implementation status

Since supply chain managers may be interested in determining the applicability of the proposed model and procedure, we included the third dimension of the taxonomy indicating whether or not the proposed model and procedure was implemented, and whether or not the model was developed based on actual data.

#### 5. SYNTHESIS AND FUTURE RESEARCH DIRECTIONS

Despite the relatively short history of CPFR, we have noticed a clear research stream established by many pioneering scholars who initiated CPFR studies during the last few years. A few of these studies worth noting include: (1) Aviv (2001) who developed a mathematical model as a means of measuring the magnitude of the benefit of joint demand forecasting and inventory planning on supply chain performance (e.g., supply chain cost); (2) Barratt and Oliveira (2001) who identified key inhibitors for CPFR implementation through an empirical survey; (3) McCarthy and Golicic (2002) who proposed managerial guidelines for successful implementation of CPFR based on their case studies; (4) Chen et al. (2000) who introduced a mathematical framework that helped measure the impact of demand forecasting on order variability (or bullwhip effect) in supply chains. Regardless of methodological differences among these studies, all of these studies share a common theme -- a verification of the positive impact of CPFR on supply chain performance (see Table 2 for detailed summaries of past CPFR studies). Following this theme, Zhao et al. (2001), Zhao and Xie (2002), Zhao et al. (2002a, 2002b), and Dejonckheere et al. (2002) attempted to evaluate the impact of demand forecasting on supply chain performance including the bullwhip phenomena using simulation models. Most of

these models, however, are confined to two-tier supply chain integration and focused their attention on supply chain costs in measuring the supply chain performance. With many open research questions unanswered and buoyed by increasing interest in CPFR, additional research is needed to consider the following areas:

- As visibility increases proportionately to the number of tiers participating in inter-organizational collaboration, future research efforts should be directed toward the development of n-tier CPFR that can support multiple supply chain partners and multiple industries. In other words, the scope of CPFR should be extended to include distributors (e.g., carriers and 3PLs) and multi-tier suppliers, while encompassing the elements of collaborative product design, transportation, event and categorical management. In particular, the integration of collaborative transportation management (CTM) into CPFR or vice versa may enhance logistics efficiency by increasing freight consolidation opportunities, updating shipment status on a real-time basis, and utilizing trucking capacity. Thus, the integration of CTM with CPFR can be an intriguing subject of future research.
- Although the potential benefits of CPFR were listed in the past literature, its success in a real-world setting has not been well documented. Additional case studies reporting the CPFR success and failure stories are needed to convince CPFR critics to consider CPFR as a major demand forecasting and planning tool. In particular, these studies should identify key enablers and impediments for the successful implementation of CPFR.
- In evaluating the magnitude of CPFR benefits, most of the existing literature relied on traditional supply chain performance measures such as inventory carrying costs and backorder costs. The development of more specific supply chain performance metrics for measuring CPFR benefits should be in order for future research. These metrics may include: cash-to-cash cycle time, inventory turns, order fill rates, and stock-out rates (see, e.g., Min and Zhou 2002 for a detailed discussion of supply chain performance metrics).
- Since CPFR is intended to bring joint benefits for all the supply chain partners involved in the demand forecasting and planning process, future research endeavors may focus on the verification of joint benefits gained from CPFR during the multiple time periods. That is to say, more longitudinal studies should be conducted to examine the long-term effects of CPFR on supply chain connectivity and visibility.
- Given the evolution of agent-based forecasting and focus forecasting that can replace or complement CPFR, the comparative analyses of CPFR versus agent-based forecasting or focus forecasting may be a fruitful area for future research. Similarly, the complementary nature of CPFR and ECR or CPFR and VMI needs to be investigated to gain further insights into the role of ECR or VMI in CPFR.

#### ACKNOWLEDGMENT

The authors would like to express sincere gratitude to the UPS Foundation for partly funding this research.

## Cooperation in Reverse Logistics

Yunfeng Zhang, Jianjing Sun

School of Management, Xiamen University, Fujian, Xiamen 361005, China  
yfzhang@126.com

### ABSTRACT

Many businesses have now realized that a Reverse Logistics system can be used to gain competitive advantage. Even the best retailers and vendors now have reason to review how their returns programs are managed. New technologies and service providers now offer an opportunity to improve overall 'total returns performance'. This means not only reducing the 'total cost of returns', but utilizing returns to improve customer loyalty, merchandising and product performance. Improving 'total returns performance' can transform an increasingly costly and complex process into a competitive advantage. It has forced businesses to reengineer their business processes and look into what can be the next practices in business rather than adopt best practices. Reverse Logistics is a very complex and specialized area of any supply chain and it involves handling individual incoming parcels, opening and inspecting products, communicating with internal departments, customers and vendors and then directing products into disposition channels which will provide the highest value. It is necessary to have a synchronized effort from all the supply chain partners for Reverse Logistics to be successful. This paper explains the various elements of reverse logistics, the need for cooperation in reverse logistics and the opportunities which arise through the processes of Reverse Logistics.

**Keywords:** *reverse logistics, cooperation, supply chain*

### 1. INTRODUCTION

Reverse Logistics by its nature is a very complex and specialized area of any supply chain. No matter what the product is, how it is sold, or who the customers are, every company needs to focus on recovering the greatest value from returns. All of this while maintaining customer loyalty, cooperation cost and harvesting information that helps reduce returns in the future. Cooperation between all supply chain partners is the key to establish the smooth flow of products and information in reverse logistics. Returns require special information systems, dedicated equipment and personnel trained in non-standard processes. Returns processing involves handling individual incoming parcels, opening and inspecting products, communicating with internal departments, customers and vendors and then directing products into disposition channels, which will provide the highest value. To create visibility in the returns supply chain a firm requires greater information sharing and using automated notification to support integrated decision making.

### 2. WHAT IS REVERSE LOGISTICS?

Reverse logistics, that is, all operations related to the extension of useful lifecycle for used products, commercial returns, excess inventory and packaging materials, gains increasing attention globally for its

promising financial potentials, its sustainable growth alternative and the environmental positive impact it could have. Reverse Logistics is a rather general term. In the broadest sense, Reverse Logistics stands for all operations related to the reuse of products and materials. The management of these operations can be referred to as Product Recovery Management (PRM). PRM is concerned with the care for products and materials after they have been used. Some of these activities are, to some extent, similar to those occurring in case of internal returns of defective items due to unreliable production processes. Reverse Logistics though refers to all logistic activities to collect, disassemble and process used products, product parts, and/or materials in order to ensure a sustainable (environmentally friendly) recovery.

Reverse logistics deals with five basic questions:

1. What alternatives are available to recover products, product parts, and materials?
2. Who should perform the various recovery activities?
3. How should the various activities be performed?
4. Is it possible to integrate the activities that are typical for reverse logistics with classical production and distribution systems?
5. What are the costs and benefits of reverse logistics, both from an economical as an environmental point of view?

Below is an example of the reverse logistics:

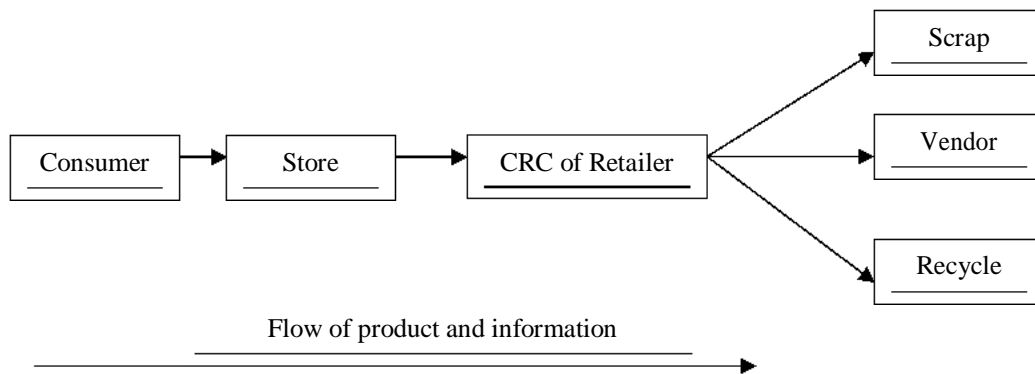

FIGURE 1: REVERSE LOGISTICS IN RETAIL INDUSTRY

### 3. FACTORS IN REVERSE LOGISTICS

#### 3.1 Zero returns

Zero Returns is a program where the company in question does not accept returns from its customer. Rather, it gives the retailer an allowable return rate, and proposes guidelines as to the proper disposition of the items. This strategy basically passes the returns responsibility onto the retailer, while reducing costs for the manufacturer or distributor.

#### 3.2 Asset recovery

Asset recovery is the “classification and disposition of returned goods as surplus, obsolete, scrap, waste and excess material products, and other assets, in a way that maximizes returns to the owner, while minimizing costs and liabilities associated with the dispositions.”

#### 3.3 Outsourcing

Many companies have established sound reverse logistics systems and procedures. In many cases, however, it makes more sense for the firm to outsource their reverse logistics functions than keep those in-house.

#### 3.4 Gate keeping

Gate keeping has been defined as “the screening of defective and unwarranted returned merchandise at the entry point into the reverse logistics process.”

#### 3.6 Compacting disposition cycle time

Disposition cycle time is the amount of time needed to figure out what to do with returned products once they arrive. Often, when material often comes back in to a distribution center, it is not clear whether the items are defective, can be reused or refurbished, or need to be sent to a landfill.

#### 3.7 Reverse logistics information systems

With the emphasis being given on Reverse Logistics today, the IT system developed to handle reverse logistics should be flexible enough for inevitable future expansion, as well as to have the ability to handle the many exceptions involved in reverse logistics. The reverse logistics system should create a database and track returns at the store level back through the pipeline to the manufacturer.

#### 3.8 Centralized Return Centers

CRC's are dedicated specialized buildings to handle returns. All of the company's customers send their returns to such a central location where the items are subsequently sorted, processed, and “disposed.” This system is essential for orderly and organized method of handling returns.

### 4. WHAT IS SUPPLY CHAIN COOPERATION?

#### Cooperation = Getting to Know You, Much Better

All trading partners have a transactional relationship, and some even share lots of information about their businesses. Cooperation goes much further to take the uncertainty out of future product supply/demand through joint planning and action. By following a specified methodology – known as Cooperation Planning, Forecasting and Replenishment (CPFR) – companies can dramatically improve supply chain effectiveness with new product and package design, demand planning, synchronized production scheduling, and logistics planning. According to the CGE&Y survey mentioned earlier, this practice is catching on: 25% of respondents indicated that CPFR has been implemented in their firms. CPFR's popularity is spreading beyond company-to-company initiatives to include industry consortia as well. Supply chain visibility and cooperation capabilities are evolving rapidly, and, not surprisingly, logistics experts often disagree on where this whole effort is headed.

### 5. WHY COOPERATION IN REVERSE LOGISTICS?

#### 5.1 Return-to-vendor adds significant and unnecessary cost.

Retailers in many industries simply send returned products back to vendor/distributors for credit. Devaluation of product as it moves backward slowly in the supply chain is dramatic. Handling, storage and shrinkage costs mount at every step of the way as the product becomes increasingly out of date. The administrative costs of managing the complex, diverse returns policies among hundreds, or even thousands of retailers, distributors and manufacturers is another major cost of return-to-vendor programs.

In an effort to reclaim some of these costs, leading retailers are now negotiating attractive “no returns” pricing with their suppliers in exchange for taking over all returns, including warranty and repairs.

### **5.2 Merchants going online are finding returns a challenge.**

With this boom in online retailing has come some chaos in all areas of customer service and fulfillment, particularly with returns. According to data from a number of industry research firms, return rates for online sales are substantially higher than traditional retailing. Rates of 20% to beyond 30% for certain categories have been reported. Most fulfillment centers, information systems and customer service centers designed for handling traditional retail simply cannot efficiently process this volume of returned merchandise. As a result, returns costs are high and returning credit to consumers has often been slow. This poor performance is a barrier to new or repeat sales to time-focused buyers.

### **5.3 The total cost of returns is high.**

The total costs associated with returns are significant. These costs are cross-functional and hit numerous expense lines, cost centers and budgets. As a result, retailers and manufacturers have difficulty measuring all of the hidden costs or fully understanding the business impact. The hard costs can, with effort, be measured. These include warehouse staff, customer service associates, shipping, storage and inventory space, third party vendors, packaging for disposition, disposal fees and other direct costs. Higher prices from suppliers for accepting returns can also be identified. The soft costs, such as customer satisfaction and loyalty, are much more difficult to measure but can have a major impact nonetheless. Retailers interviewed recently believe that the total cost of returns could be as much as 5-10% of sales.

### **5.4 Value recovery from returns has traditionally been low.**

There are a number of established methods for recapturing some value from returned merchandise. In-store sales and return-to stock are labor intensive, provide mixed results and also pose risks to brand

equity and cannibalized sales. Traditional liquidation channels have provided low value recovery—often only 10%-20% of retail value due to slow and inefficient paths back to consumers. The Internet has enabled new channels for selected merchandise that offer more direct, faster resale paths with higher recovery.

## **6. Why focus on Reverse Logistics?**

Following are a few forceful reasons to focus on Reverse logistics:

### **6.1 Return rates are higher than ever.**

Return rates are high and climbing, especially for online businesses which are experiencing increased return rates as a result of trial and impulse Internet purchasing. Calls and traffic to customer service also increases as online buyers, in particular, expect fast credits and refunds.

### **6.2 The cost of returning items to vendors is ultimately absorbed by retailers.**

Retailers in many industries simply return products to vendors. Sending more products back to vendor's results in necessary price increases to their customers, the distributors and retailers.

### **6.3 Do third party logistic providers handle returns efficiently?**

Some retailers have successfully outsourced fulfillment and logistics functions to third parties for better service, lower costs and increased flexibility. However, few of these providers have yet to develop the special processes or to make the incremental investments necessary to handle returns efficiently.

### **6.4 Taking full-Advantage of new returns technology is the key.**

New technologies and service providers have emerged to address the increasing demand for better solutions in returns management.

### **6.5 Returns as a competitive advantage.**

Retailing has become competitive, so every opportunity should be taken for bottom-line improvements. Returns have the potential to be one of the greatest untapped sources for increased revenue and customer loyalty.

### **6.6 Returns: not just a necessary cost of doing business.**

Returns have traditionally been considered just a necessary cost of business. However, the costs associated with returns are far from trivial when all of the hard and soft costs are calculated to determine true business impact.

### 6.7 The traditional liquidation of returns channels are slow, inefficient and costly.

Recovering value from returns is a difficult task through the traditional liquidation channels. Although these channels are widely used, they lack ease and efficiency, and the end result for merchants is the recovery of a mere 10 to 20 percent of cost. Products lose value at every step to final disposition.

### 6.8 Returns contain a wealth of information on products and merchandising.

Returns offer an immense amount of information about consumers and products that few retailers and merchants capture. For example, returns can provide information about the original merchandising, actual product performance, ease of use, product defects and consumer expectations.

## 7. COOPERATION IN REVERSE LOGISTICS

### 7.1 Warranty

The first steps towards collaboration need to be taken while dealing with warranty at the *customer-retailer interface*. Any product with a lapsed warranty should not be allowed into the reverse supply chain by retailers: such products consume time and effort in the reverse supply chain. If the product enters the supply chain it needs to be dispositioned – recycled, refurbished or returned deciding the appropriate course of action is a potential area of conflict at the retailer-vendor interface. Verification of products at the store level may be done using invoices or serial number of product. However, this is easier said than done because tracking of millions of individual items requires maintaining a large database which proves inefficient, retrieval of information is time consuming and not cost effective.

The next stage for collaboration comes at the *retailer-vendor interface*. Once the product is accepted by the store it is moved to the CRC of the Retailer. There generally is some time gap between these two events. This delay may be due to a minimum return quantity stipulated by the retailer to stores or specified time periods during which returns are accepted. For any product accepted close to the end of warranty, its warranty may expire during this time delay. Hence, information systems at the CRC should be responsive and raise exceptions and alerts to warn the retailer and expedite the returns process. The system should check if demand for this product exists elsewhere in the network of stores and accordingly arrange for movement of stocks. FIGURE 2 show the details.

### 7.2 Return Material Authorization (RMA)

Cooperation would be required between vendors and

retailers to ensure the flow of products in reverse logistics. It is important that they understand specifics of the return supply chain and agree on disposition of returned products. To ensure this cooperation information on daily returns needs to be available centrally to both the retailer and vendor so that they may optimize the frequency and cost of transportation.

### 7.3 Return price rationalization

For any product in the retail chain two prices come into play. First, the price paid by the retailer to the vendor and second, the price a customer pays to buy the product.

Customer-Retailer interface: On returning a product, customers demand a reimbursement from the retailer. The retailer is hence obliged to pay the customer at the price at which the product was bought. However, customers may have misplaced or lost the invoice making it impossible to verify the price for reimbursement. Two cases emerge from this scenario:

(i). Reduction in price of product after it was first purchased. Owing to lack of information, customers are reimbursed at the reduced price, they suffer a loss. This leads to loss of face of the retailer and a loss in customer loyalty and brand image of the retailer.

(ii). Reduction in price of product after it was first purchased. In this case the retailer is at a loss since he has to reimburse the customer at a higher price. The retailer hence suffers a financial loss on the return in question.

Hence, it is important to be able to track the price of individual products while being returned by customers. Serial number tracking could be the answer to resolve this issue.

Retailer-vendor interface: Once the product is in the reverse supply chain and the retailer needs to return the product to the vendor an important question arises, at what price should the vendor reimburse the retailer?

### 7.4 Product returns with damaged packaging

Many a time products returned by customers to retailers or vendors are not in the original package. Either the package in which the product is returned is damaged or is of a different product all together. This creates problems in reverse logistics since any identification put on the product is lost and products are not in a position to be identified by any scanning media leading to a discontinuity in information flow in the supply chain.

At the retailer-customer interface: Retailers may refuse to accept products not returned in the original packaging, this leads to friction between customers and retailers which ultimately results in an irate customer thereby affecting customer satisfaction, retention and loyalty and diminishing the brand equity of the retailer.

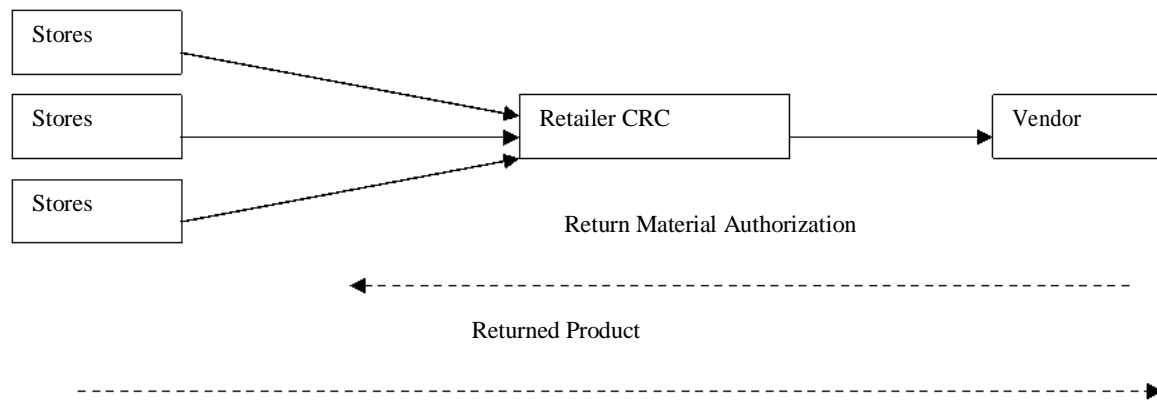

FIGURE 2: FLOWS IN SUPPLY CHAIN

## 8. CONCLUSION

Reverse Logistics has been stretching out worldwide, involving all the layers of supply chains in various industry sectors. While some actors in the chain have been forced to take products back, others have pro-actively done so, attracted by the value in used products. One way or the other, therefore, Cooperation in Reverse Logistics has become a key competence in modern supply chains.

### ABSTRACT

Supply chain management has been influenced greatly by e-business, so does coordination which is regarded as the core of supply chain management. The characteristics of supply chain management based on e-business are analyzed firstly, which describe that information transmission has been accelerated and the relation between enterprises has become not only competitive but also cooperative under e-business environment. Differences of coordination mechanism between tradition environment and e-business environment are compared secondly. Finally, according to market relation and competitive-cooperative relation between enterprises, the suitable coordination mechanisms based on e-business are put forward. The paper presents a framework to assist managers in adopting the suitable coordination mechanisms under different business environment.

**Keywords:** Supply chain management, E-business, Coordination mechanism, Cooperative relation

### 1. INTRODUCTION

Supply chain management (SCM) has gained significance as one of the 21st century manufacturing paradigms for improving organizational competitiveness. Emphasizing strategic collaboration, information sharing, responding to market rapidly etc, the key of supply chain management is to manage and coordinate the cooperation between enterprises of supply chain. However, because the application of the network and information technology lags behind the relative advanced management mode, the traditional supply chain based on paper, fax, is difficult to share information simultaneously between enterprises. Though some manufacturing companies have adopted the systems, such as MRPII, ERP, CRM, DSS, etc, the systems can't fully support and reflect the strategic advantage and systematic characteristic of supply chain management. These systems are often limited in single enterprise and the Online Electronic Linkage between partners and the interface between the enterprise and customer are weak, which lead to the lone island of information of supply chain.

E-business is a kind of social form of business operation using modern computer information technology, especially network technology. The basic purpose of e-business is to realize the maximization of the social wealth through improving productivity, reducing the operating costs, optimizing resource distribution. The rise of e-business is a revolutionary of the business operation mode caused by the rapid development of information technology, which leads to the great change in existence foundation, operation way, management mechanism of traditional economic activity, then the traditional market ideas, and then the theories and methods of supply chain management. As a result, e-supply chain management appears being the combination of e-business and supply chain

management.

As one of new management modes, supply chain management integrates and coordinates resources of all nodal enterprises, so coordination is the core of supply chain management. Under e-business environment, the communication in organization becomes more convenient. And the institutional structure is a hierarchical network system, which make the range of management bigger and the amount of information that the members need to accept and deal with older. In addition, carrying on customer relation management and establishing learning organization make it difficult to obtain, share and integrate the information in the supply chain. Because the uncertainty of market is increasing under e-business environment and the relation between partners becomes complicated, partners will often intend to conceal the information or the knowledge resources in consideration of one's own interests. At the same time, with the application of e-business, managers can set up various coordination mechanisms through network. Using the appropriate coordination mechanisms offers the potential to help managers improve business performance, increase revenues, reduce costs and reach new markets. However, for these to happen, management practices must be adapted to the new environment. The Internet facilitates the implementation of a variety of coordination mechanisms, such as auctions, electronic agents, etc. The challenge that the managers face is to choose the mechanism that best fits each situation. So grasping the coordination mechanisms of supply chain based on e-business is very important to go on the deeper research of supply chain management and has great directive significance to apply the thoughts of supply chain management to our country.

The purpose of this paper is to identify which coordination mechanism is best fit to the practical business environment. At first the characteristics of

supply chain under e-business environment are analyzed. The differences of coordination mechanisms between tradition environment and e-business environment are compared from running environment, feedback mechanism etc. Then the suitable coordination mechanisms under e-business environment are put forward and compared. The text is summarized finally.

## 2 SUPPLY CHAIN MANAGEMENT BASED ON E-BUSINESS

With the improvement of information technology and the aggravation of economic globalization, the development of e-business is very fast. As the statistics of relevant materials showing, the global turnover of e-business reaches 15,300 million Yuan in 1998, rises to 26,500 million Yuan in 1999, increases about 73% per year on average. E-business is concerned by all walks of life, and management theories and operation modes have changed deeply.

### 2.1 Characteristics of Supply Chain Management Based on E-business

Supply chain management has been influenced by e-business. Manufacturers can sell products to consumers directly not having dealer or the retailer through e-business, which eliminate some unnecessary links of supply chain. Meanwhile, the information flow and fund flow between enterprises are more frequent. The relation between enterprises has changed. Therefore, under e-business environment, supply chain management has some new characteristics.

#### 1) The complication of relation between enterprises

Traditional supply chain regards production as the centre. Because of the existence of the seller's market, the seller can control the buyer through price and quantity of supply, and the relation between buyer and seller is a kind of short-term contract, that is a kind of competitive relation. Because of the appearance of advanced management thought, such as MRP, JIT, TQM, etc., the relation between enterprises changes into the logistic relation progressively. The main characteristic of logistic stage is the integration of enterprises based on material. The cooperative relation of enterprises based on logistics is only a basic cooperation.

With the appearance of e-business, the cooperation between enterprises of supply chain has been strengthened. Not only the material flow, but also the information flow is transferred between enterprises. Strategic cooperative relation appears. The relation between enterprises of supply chain is becoming more complicated which is not only competitive but also cooperative.

#### 2) Enhancement of information sharing

The purpose of information integration is to realize information sharing of supply chain enterprises, reduce the influences of uncertain factors. The information transmission of traditional supply chain is a chain which can easily lead to "bull whip effect". After e-business appears, supply chain management is set up a centre of information management based on Internet which is a mode of network information integration. It can store all kinds of data, and deal with information in time. It is helpful to realize the cooperation between enterprises and improve the integration of information in the supply chain.

#### 3) Realization of synchronized operation

The synchronized operation between enterprises of supply chain can reduce the delay of demand information, improve the working efficiency. Because of the distorting of information transmission and the relation of competition between enterprises, the traditional supply chain is very difficult to take operation in step. Under the environment of e-business, the synchronization can be realized by Internet. Through Internet, enterprises can forecast, make and implement the relevant plan together. Meanwhile, buyers and sellers can share the result of forecasting, exchange the views and coordinate the difference of both sides in time. Therefore, supply chain management can realize the synchronization entirely on internet.

#### 4) The transformation of management focus

Under the traditional mode of management, the focus of supply chain management is how to create value using the advantage of production technology and management. In e-business era, the focus of supply chain management is how to assure "power origin" status of consumers, how to obtain knowledge through an analysis of uncertain demand, and how to create value by sharing knowledge with the whole supply chain. So the supply chain enterprises should collect and share of demand information, and change them into knowledge which can improve the efficiency of supply chain by the knowledge converter.

#### 5) pull-operational mode of supply chain

The operational mode of traditional supply chain is a typical kind of push management. After having produced goods, manufacturers send them to retailer or customer by utilizing logistics. In this course, the trade flow and material flow are push management. The logistics doesn't create value by itself but only plays the function of supporting while the whole goods move. However, supply chain based on e-business is different. Because the activities of commodity production, distribution, storage and delivery are all operated according to the customer's order, all the activities including trade flow, material flow and fund flow are all connected with market. Logistics has not only offered a

strong guarantee for trade flow, but also created value at the same time because it is the component of the customer service.

#### 6) The appearance of virtual market

In e-business era, the living space of enterprises has changed to not only physical market but also virtual market. The virtual market is based on information, and controlled by information. The appearance of virtual market has changed the situation that consumers must use or enjoy products / serve through the physical market, and weakened the restriction that producers must gain and produce resources through the physical market. Physical value chain which enterprises depend on in the supply chain becomes virtual. Enterprises can seek new points of creatable value by the information technology such as integration, organization, choice and synthesizing etc.

### 2.2 Comparison of Coordination Mechanisms between Traditional Supply Chain and E-business Supply Chain

Coordination is the administrative behavior based on the communication of information. With the appearance of e-business, the communication of supply chain enterprises becomes more convenient. A lot of new information sharing platforms have been used. Many new coordination mechanisms are presented, such as on-line auction, electronic agent and VMI etc. At the same time, because of the improvement of information technology and the expansion of economic globalization, the relation between supply chain enterprises has not only competitive but also cooperative. So there are differences of coordination mechanisms between traditional supply chain and e-business supply chain.

#### 1) Running environment

Traditional coordination mechanisms are mainly considered the internal coordination of single enterprise which cope with uncertain market under fixed environment. Therefore the coordination mechanisms survive in a "steady" environment. Under the environment of e-business, information sharing between enterprises of supply chain is more frequent. In order to reply the changeable market quickly, rational coordination mechanisms must be set up between enterprises of supply chain. However, the change of decision for any enterprise will cause the difference of decision for other enterprises because of interdependence of supply chain enterprise. The coordination mechanisms must be fit for dynamic environment. The coordination mechanisms should be made by considering the uncertain factors of environment of supply chain management, so that the supply chain can deal with the market quickly and

effectively.

#### 2) Decision mode

There are two kinds of decision modes for the coordination mechanisms of traditional supply chain: centralized decision and distributed decision. Centralized decision supposes that the decision center can get information of all relevant enterprises or departments, and make relevant decision based on all information. Distributed decision is another kind of extreme form of decision mode, and the decisions are made by each enterprise or department according to their own information. Under the environment of e-business, depending on information technology, information can be transmitted fast among enterprises, the operation of synchronization among enterprises will be realized, and the purpose of responding to market and meeting customer's demand will be achieved. But the real supply chain is often a competitive-cooperative system formed by different enterprises whose purpose is to maximize their own interests, so the key enterprise can not obtain all information needed. While setting up the coordination mechanisms, enterprises should consider both their own existing information and the information of partners that can be received, which can expand the whole optimization space of supply chain.

#### 3) Feedback mechanism

The implementation of any system must set up a feedback mechanism of information. The implementing quality of coordination mechanism is strongly connected with the feedback mechanism. The traditional feedback mechanism is a type of chain. The feedback of information is transmitted from one department to another, which forms a parallel mode of information transmission with organizational structure. Supply chain based on e-business has a feedback mechanism having the characteristics of network. The information of enterprises is transmitted not according to the organizational structure, but the different enterprises in the supply chain. Because the organizational forms of enterprises in the supply chain are different, the forms of information flow are different.

#### 4) Transparent degree

The enterprise of traditional supply chain which regards their own interest as the center neglects the information and interests of partners. The coordination method adopted is mainly to optimize one's own interests. Under the environment of e-business, there is very strong cooperative relation between enterprises. The information of all enterprises of supply should be considered while making decisions. The coordination mechanisms of enterprises should have heavier transparency in order to gain the synchronal operation in the supply chain.

### 3 COORDINATION MECHANISMS BASED ON E-BUSINESS

Under the environment of e-business, information sharing between enterprises of supply chain management is increasing, and relation between enterprises is different. For example, ShiHua Ma divides the partner's type into four kinds from both increment function and competitiveness: strategic cooperative partner, competitive / technical cooperative partner, powerful cooperative partner, and ordinary cooperative partner. Kim Langfield-Smith divides it into three kinds: non-cooperation, short-term cooperation, close cooperation and cooperative network relation. So in order to stimulate partners effectively, different coordination mechanisms should be applied to different partners. The paper presents the suitable coordination mechanisms under e-business environment according to market relation and competitive-cooperative relation.

#### 3.1 Market Coordination Mechanisms

Market coordination is used to conduct a business transaction, to purchase something at a given price. Frequently, market coordination is used to foster price competition among potential suppliers. Therefore, market transactions are often one-time transactions because a different supplier can be selected for each transaction. The information that is shared using market coordination is generally limited to the conditions of the transaction, delivery information and payment, in addition to bidding processes. Usually, market coordination will not provide a sustainable competitive advantage to a firm. Nonetheless, they tend to be simple to use and frequently offer the opportunity to purchase some items at a lower price, making them popular. We identify two market coordinative mechanisms: on-line coordination and Electronic agents.

On-line auction is a market mechanism in which the buyers and seller agree on the item to be auctioned, and on payment and delivery conditions. Under the environment of e-business, auction has new characteristics. Firstly, no relation-specific assets between buyer and seller are needed in an on-line auction on the internet. Secondly, because auctions are one-time transactions, the transaction risk is low and the operational performance risk for auctions can be high. Finally, since the preparation for and the participation in an auction is time consuming, the frequency of transaction needs to be low. Higher frequency might make other coordination mechanisms preferable.

Electronic agents that focus on studying the coordination mechanism between the entities are the core in the field of the distributed artificial intelligence in recent years. They connect commercial goal with customer's interests to reduce the transaction costs between buyers and sellers automatically. Electronic agents are part of the IT infrastructure since they are used for doing business with all possible customs or

suppliers. There are no relation-specific assets. Further, automated transactions are one-time transactions, which makes the transaction risk low. For the same reason, operational performance risk is considered medium to high.

#### 3.2 Competitive-cooperative Coordination Mechanisms

With the violence of market competition, the relation between enterprises changes to competition and competition-cooperation. Because the foundation of coordination is cooperation, market mechanism can be adopted under competitive relation, while competitive-cooperative coordination should be applied under competitive-cooperative relation. The contents of competitive-cooperative coordination include not only price, but also time, quantity, planning, stock, etc. coordination. Implementing competitive-cooperative coordination requires medium asset specificity, which is lower than implementing an EDI link, but it is higher than implementing other market mechanisms. Transaction risk due to closeness of the relation is high given that competitive-cooperative coordination is generally implemented with key members of the supply chain. Operational performance risk is low since management may implement coordination to actively manage the relation and, ultimately, to reduce risk of operational failure. Two competitive-cooperative coordinative mechanisms are identified: stock coordination and planning coordination.

Stock coordination can improve the systematization and integration of supply chain, and strengthen the agility and response of enterprise through controlling the inventory. The emphasis of stock coordination is to reduce "bull whip effect" caused by the separating stock of enterprises and improve synchronization of supply chain. Stock coordination that reflects new-type cooperative relation of supply chain is a stock management of risk sharing

Planning coordination is a new-mode of supply chain coordination mechanism and is considered requiring high cooperative degree between enterprises. It emphasizes the information sharing that should carry on from drawing up to implementation of the plan between enterprises, which increase the whole flexibility of supply chain.

### 4 CONCLUSIONS

With the development of e-business, information transmission between enterprises of supply chain becomes faster and faster. At the same time, the relation between enterprises changes into not only competition but also cooperation. So supply chain management changes greatly, and as the core of supply chain management, coordination has heavy difference too. Firstly, the influences of supply chain management that

are brought into by e-business are analyzed. Secondly, the differences of coordination mechanisms between traditional environment and e-business environment are compared. Finally, the suitable coordination mechanisms under e-business environment are put forward. There are positive impetuses for the administrator to identify the suitable coordination under all kinds of business environment. Applying different coordination mechanisms to different partners can greatly improve the performance of supply chain.

## ABSTRACT

Compared with traditional information system development methodology, COTS-based information system has the following advantages: Avoid expensive development and maintenance; frequent upgrades often anticipate organization's need; rich functionality; mature technologies; tracks technology trends, etc. However, how to select appropriate COTS components is a complex problem. For improving the accuracy of decision-making in COTS component procurement, a two-period model is put forward. In the first period, the procurement requirement of each COTS component is compared with a COTS component case base by case-based retrieval (CBR) and the initial candidates are selected. In the second period, a (0-1) integer goal programming model is created to optimize cost and time of the whole COTS-based system, and help decision makers to decide the final candidates. Case shows that the two-period method declines the complexity of computation and increases the rationality of decision.

**Keywords:** COTS (Commercial Off-The-Shelf), component procurement, case-based retrieval, goal programming

## 0 INTRODUCTION AND BACKGROUND

COTS (Commercial Off-The-Shelf) component is a kind of software product that has the following characteristics [1]:

- ò Sold, leased, or licensed to the general public;
- ò Offered by a vendor trying to profit from it;
- ò Supported and evolved by the vendor, who retains the intellectual property rights;
- ò Available in multiple, identical copies;
- ò Used without source code modification.

Compared with traditional information system development methodology, COTS-based solution has the following advantages: Avoid expensive development and maintenance; frequent upgrades often anticipate organization's need; rich functionality; mature technologies; tracks technology trends, etc [2].

A lot of organizations and scholars have done a series of research on COTS component in recent years. The European Union's Framework V programme has funded a series of new research initiatives in component-based software engineering (CBSE) [3]. Gardler et al. [4] research how to support component-based software evolution at strategic level of e-Business. Maiden et al. [5] discuss how to acquire COTS software selection requirements. Some scholars give guidance about COTS component evaluation and selection [6,7,8]. Sundarraj et al. [9] create a multi-period optimization model for the procurement of component-based enterprise information technologies.

The optimization model for the procurement of COTS component given by Sundarraj considers both component procurement cost and inter-component integration cost. That makes decision more scientific.

However, the model cannot explain how to deal with the attributes difficult to be described quantitatively. In this paper, the kind of attribute is considered and a two-period decision model for COTS component procurement is given. In the first period, initial candidates are selected by case-based retrieval (CBR). In this period, the procurement requirement of each COTS component is viewed as a new problem and is compared with a COTS component case base. Of course, a COTS component case base should be created in advance by collecting information from component marketplace and scoring attributes for each COTS component. In the second period, final candidates are selected by (0-1) integer goal programming from initial candidates.

## 1 COTS-BASED SOFTWARE SYSTEM

A COTS-based software system means that the software system is developed by purchasing and integrating COTS components. Compared with traditional system, a COTS-based software system has longer analysis and design phases, whilst the implementation phase focuses on COTS component integration rather than on programming [4]. In implementation phase, the main task is inter-component integration. The glue code programming averagely is 37% of effort required to complete various COTS-based development activities [10].

A process model [4] for developing COTS-based e-Business system is shown in Figure 1.

E-Business Maturity Model (EBMM) is a strategic positioning and planning tool. Pattern library stores software patterns mapping business patterns that represent e-business "best-practice" processes. In analysis and design phase, EBMM is applied to export

business patterns mapping business strategy and pattern library is used to export software patterns mapping business patterns. After analyzing the software patterns, component procurement requirements are acquired. In

implementation phase, according to requirements, components are tested and purchased, and then, system is developed by components integration.

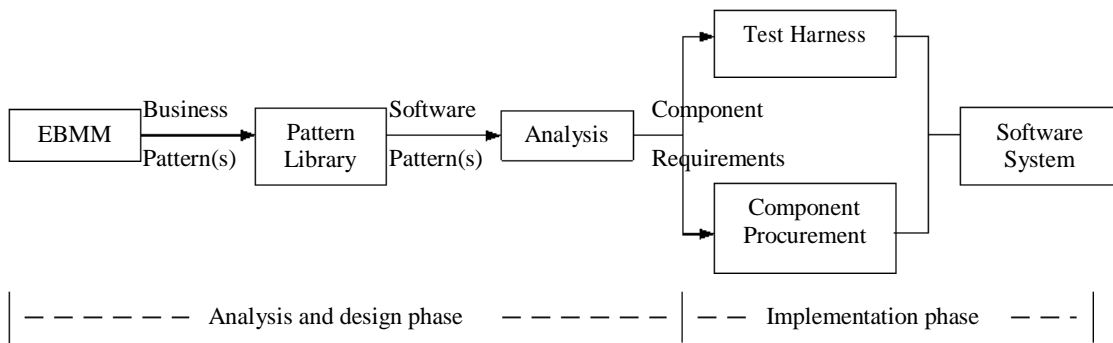

Figure 1 Process model for developing COTS-based e-Business system

In this paper, the work mainly focuses on the component procurement decision activity in implementation phase. On the basis of component requirements, CBR and goal programming are applied to create a two-period decision model.

The details about the model are given in Section 2.

## 2 MODEL

COTS component procurement decision-making is a complex process. In the process, large numbers of attributes should be considered comprehensively. Some attributes are shown in table 1.

Table 1 The attribute of COTS component

Category	Attribute
Technical	Application domain
	Architecture level
	Architecture compatibility
Quality	Functionality
	Reliability
	Usability
	Efficiency
	Maintainability
	Portability
	Effectiveness
	Productivity
	Safety
	Satisfaction
Vendor	Capability maturity level
	Market share
	Market size
	Market stability
	Financial viability
	Management viability
	R&D viability
	Product support
	Vendor reputation
	Training
	Delivery time
	License type
Cost	Acquisition cost
	Ownership cost

According to whether easy to be described quantitatively, attributes are categorized into two groups: quantitative ones and non-quantitative ones. Quantitative attributes, such as cost and time, satisfy additivity principle and are easy to get solution by goal programming. Non-quantitative attributes, such as functionality, are non-additivity and not easy to be applied to goal programming. In this paper, CBR is used to aggregate the non-quantitative attributes.

In section 2.1, the method how CBR is applied to candidate selection is introduced in detail. In section 2.2, the goal programming model is given.

### 2.1 CBR(Case-Based Retrieval)

Nowadays, there is no uniform and accepted approach for COTS component procurement decision-making. We find that selecting components from marketplace is similar to retrieving components from case base in principle. So, CBR is applied and a nearest neighbor retrieval function is given as formula (1) shows[11] :

$$\frac{\sum_{i=1}^n W_i \times \text{sim}(f_i^I, f_i^R)}{\sum_{i=1}^n W_i} \quad (1)$$

Where  $W_i$  is the weight of attribute  $i$ ,  $\text{sim}()$  is similarity function, and  $f_i^I$  and  $f_i^R$  are the values for the attributes of the input and retrieved cases. The retrieved case with a higher aggregate match score represents the nearer match.

Initial candidates are selected from COTS marketplace according to the threshold  $\beta$  defined in advance.

### 2.2 Goal Programming

Integer goal programming is applied to select the final candidates from initial candidates. Two main quantitative

objectives, cost and time, are considered.

The total cost of a COTS component is made up of acquisition cost and ownership cost. Acquisition cost includes price and procurement expense. Ownership cost mainly includes inter-component integration cost.

The total Time is composed of delivery time and inter-component integration time.

The (0-1) integer goal programming model is given as follows:

$$\begin{aligned} \text{Min } & w_1 v_1 + w_2 v_2 \\ \text{s.t. } & \end{aligned}$$

$$\sum_{j=1}^{J_i} \sum_{i=1}^I (p_i^j + e_i^j) x_i^j + \frac{1}{2} \sum_{j \neq j'} \sum_{i' \neq i''} c_{i' i''}^{j j'} x_{i'}^{j'} x_{i''}^{j''} - v_1 = c_{\min}$$

$$\sum_{j=1}^{J_i} \sum_{i=1}^I t_i^j x_i^j + \frac{1}{2} \sum_{j \neq j'} \sum_{i' \neq i''} t_{i' i''}^{j j'} x_{i'}^{j'} x_{i''}^{j''} - v_2 = t_{\min}$$

$$\sum_{j=1}^{J_i} x_i^j = 1 \text{ for all } i \in I$$

$$\sum_{j=1}^{J_{i'}} x_{i'}^{j'} = 1 \text{ for all } i' \in I$$

$$\sum_{j=1}^{J_{i''}} x_{i''}^{j''} = 1 \text{ for all } i'' \in I$$

$$x_i^j, x_{i'}^{j'}, x_{i''}^{j''} \in \{0, 1\}$$

$$v_1, v_2 \geq 0$$

$$w_1, w_2 \geq 0$$

Notation:  $p_i^j$  is the price of candidate component  $M_i^j$ ;  $e_i^j$  is the procurement expense of component  $M_i^j$ ;  $c_{i' i''}^{j j'}$  is the integration cost of component  $M_{i'}^{j'}$  and component  $M_{i''}^{j''}$ ;  $t_i^j$  is the delivery time of component  $M_i^j$ ;  $t_{i' i''}^{j j'}$  is the integration time of component  $M_{i'}^{j'}$  and component  $M_{i''}^{j''}$ ;  $i, i', i'' \in I$ ;  $I$  is the set of component requirement areas that needed to be covered;  $j, j', j'' \in J_i$ ,  $J_i$  is the set of candidate components for component requirement area  $i$  ( $i \in I$ );

$$x_i^j, x_{i'}^{j'}, x_{i''}^{j''} = \begin{cases} 1, & \text{if } M_i^j, M_{i'}^{j'}, M_{i''}^{j''} \text{ is selected} \\ 0, & \text{otherwise} \end{cases};$$

$v_1, v_2$  is the eccentricity coefficient;  $w_1, w_2$  is the weight of  $v_1, v_2$ ;  $c_{\min}$  is the limitation of total cost;  $t_{\min}$  is the limitation of total time.

### 3 EXAMPLE

Assume that company  $H$  has three COTS component requirement areas:  $A$ ,  $B$ , and  $C$ . The inter-component integration relationship is  $A \rightarrow B \rightarrow C$ . Namely,  $A$  links with  $B$  and  $B$  links with  $C$ . The candidate set of  $A$  is  $\{A1, A2, A3\}$ . The candidate set of  $B$  is  $\{B1, B2, B3\}$ . The candidate set of  $C$  is  $\{C1, C2, C3\}$ .

In the first period, initial candidates are selected by CBR.

The similarity function is defined as formula (2).

$$\text{sim}(f_i^I, f_i^R) = 1 - \frac{|f_i^I - f_i^R|}{f_i^I, f_i^R \in [0, 1]} \quad (2)$$

Because requirement areas are viewed as frame of reference to score, we can assume the values for attributes of each requirement area have been standardized, namely,  $f_i^I \equiv 1$ . Then, formula (2) can be simplified as formula (3).

$$\text{sim}(f_i^I, f_i^R) = f_i^R \quad (3)$$

The amount of attributes is large in practice. For simplifying computation, only four attributes—functionality, reliability, safety, product support degree—are considered in this example. In table 2, the values of attributes are given by score method.

Table 2 The values for attributes

	Functional -ity	Reliability	Safety	Product support degree
A1	1.0	0.9	0.9	0.9
A2	0.9	0.8	0.8	0.8
A3	0.8	0.8	0.7	0.6
B1	0.8	0.9	0.8	0.9
B2	0.9	0.9	0.9	0.9
B3	0.7	0.6	0.7	0.8
C1	0.8	0.8	0.9	0.9
C2	0.9	1.0	0.9	0.9
C3	0.9	0.8	0.9	0.8

The weights of four attributes are 0.4, 0.2, 0.2, and 0.2 in turn. The threshold  $\beta$  is 0.8. Input the data above into formula (1) and formula (3). The result shows that A3 and B3 should be removed from candidates. Therefore, A has two choices  $\{A1, A2\}$ ; B has two choices  $\{B1, B2\}$ ; and C still has three choices  $\{C1, C2, C3\}$ .

In the second period, final candidates are selected by (0-1) integer goal programming. The data in tables below is given by Delphi method.

Table 3 Inter-component integration cost (hundred \$)

	A1	A2	B1	B2	C1	C2	C3
Price (hundred \$)	65	75	20	18	45	40	43
Procurement expense (hundred \$)	6.5	7.5	2	1.8	4.5	4	4.3
Delivery time (hour)	10	15	18	12	6	9	12

Table 4 Inter-component integration time (hour)

	A1	A2	B1	B2	C1	C2	C3
A1	0	0	3	2	0	0	0
A2	0	0	2.5	2.8	0	0	0
B1	3	2.5	0	0	2	1	2
B2	3	2.8	0	0	2	1.6	1.5
C1	0	0	2	2	0	0	0
C2	0	0	1	1.6	0	0	0
C3	0	0	2	1.5	0	0	0

Table 5 Price, procurement expense, and delivery time

	A1	A2	B1	B2	C1	C2	C3
A1	0	0	1	2	0	0	0
A2	0	0	1.5	0.8	0	0	0
B1	1	1.5	0	0	1	1.5	2
B2	2	0.8	0	0	1	0.8	1.5
C1	0	0	1	1	0	0	0
C2	0	0	1.5	0.8	0	0	0
C3	0	0	2	1.5	0	0	0

$$w_1=0.75, w_2=0.25, c_{min}=130, t_{min}=30.$$

Input data above into goal programming model and the result is  $v_1=8.9$ ,  $v_2=3.8$ ,  $w_1v_1+w_2v_2=7.625$ . The final candidates—A1, B2, and C2—are purchased.

#### 4 CONCLUSIONS AND EXTENSION

According to different features, the attributes of COTS component are categorized into quantitative ones and non-quantitative ones. To non-quantitative attributes, CBR is applied to aggregate the evaluation values. To quantitative attributes, goal programming is applied to decide the final candidates. The two-period method declines the complexity of computation and increases the rationality of decision. A series of extensions are possible with the work described in this paper. Firstly, the collection of data may be more scientific and the sensitivity of parameters should be analyzed. Secondly, for a large-scale system, the computing would be

complex and efficient solution algorithms should be developed. Finally, the issues about decision support system aiding COTS component procurement decision-making are worth to be researched more deeply.

## Design of an E-SCM system for Auto-Parts Companies

Junsu Lee, Jaebung Rhu, Kiseong Kim, Myunghyun Oh, Jongyeong Lee, Byungho Jeong  
Dept. of I&IS Eng., Chonbuk University, Chonju, Chonbuk, 561-756, Korea

### ABSTRACTS

This paper deals with the design of e-SCM for a supply chain of a commercial vehicle company. Two first vendors and two second vendors of the company are included in the objects of developing e-SCM system. We analyzed the information flow and business process between 1st vendor and 2nd vendors. The database (DB) has to be designed for contents of easy access, correction and update, because DB is indispensable for developing the new system. A relational database concept was used to design tables which maintain data needed in the system. The paper uses data flow diagram to describe TO-BE model of the e-SCM system.

**Keywords:** e-SCM, SCM, VMI

### 1. INTRODUCTION

Intensive competition in recent global markets, the introduction of products with short life cycles and the heightened expectations of customers have forced business companies to focus their attention on their supply chain. In a typical supply chain, raw materials are purchased, items are produced at one or more factories, shipped to warehouses for intermediate storage, and then shipped to retailers or customers. In this context, supply chain management(SCM) is a set of approaches utilized to efficiently integrate suppliers, manufacturers, warehouses, and stores, so that an end item is produced and distributed at the right quantities, to the right location, at the right time, in order to minimize system wide costs while satisfying service level requirements [1, 5]. The supply chain of a commercial vehicle company has more complex procurement chain. It is most important to manage the procurement process of auto

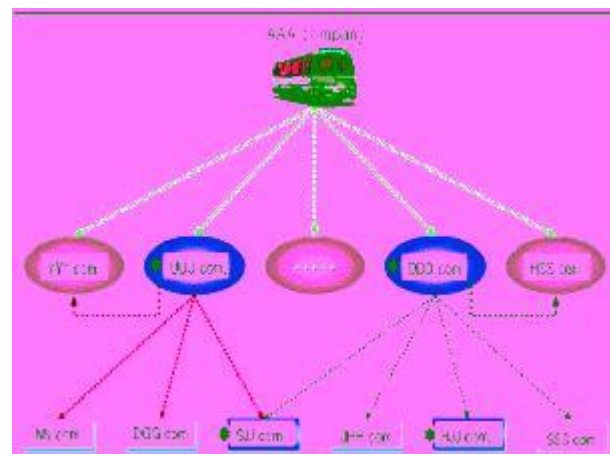

parts in the supply chain of a commercial vehicle company. Thus this paper deals with the design of an e-SCM system for small and medium size auto-part companies that are the first and second vendors of a commercial vehicle company.

The SCM system has to be designed in integrated point of view to be used successfully [2, 3]. Even though every researcher defines the integration differently, in general, supplier integration, alignment of purchaser and supplier, coalition between suppliers, and supply chain synchronization are included in the concept of integration [4]. In those senses, the supply chain of a commercial vehicle industry is more complex than those of other industries and especially, a procurement supply chain is relatively important in the industry. However, from the characteristics of domestic industrial environment, the relations with a vehicle company and its vendors forms a hierarchical supply chain structure with dependency rather than cooperative independency. Since the competitive power of a vehicle industry depends on the competitive power of whole supply chain rather than that of the industry itself, we need the effective methods to manage the whole supply chain

including the procurement supply chain reasonably. Thus, this paper dealt with analysis of business process and information flow, system design for developing e-SCM system of some auto-part companies. Section 2 provides a brief overview of sample supply chain. Section 3 describes the results of AS-IS analysis to understand intra-company business process and inter-company data flows. The TO-BE model is given for design of e-SCM system based on previous results in section 4.

### 2. SELECTED PROCUREMENT SUPPLY CHAIN FOR DEVELOPMENT OF AN e-SCM SYSTEM

Four auto part companies are selected to develop the e-SCM system in this study. Two of them are the first vendors and others are the second vendors of company 'AAA' which assembles trucks and buses. A company 'UUU' is the first vendor and has about 50 employees.

\*: companies to be considered in this research

< Figure 1> A sample supply chain for procurement of the vehicle company

The roof of buses is main item which the company 'UUU' produces and supply for the company 'AAA'. Some of other first and second vendors of the company 'AAA' furnish the company 'UUU' sub-parts that are

required to make the roof of buses. A company 'DDD' is also one of the first vendors of the commercial vehicle company 'AAA' and about 60 employees work for this company. The main products are a frame of buses and bumpers of trucks. The sub-parts for frames and bumpers are made for itself or are supplied from other first and second vendors of 'AAA'. The second vendors 'SJJ' and 'HJJ' are included in the procurement supply chain of this study. <Figure 1> shows the part of the supply chain for this study.

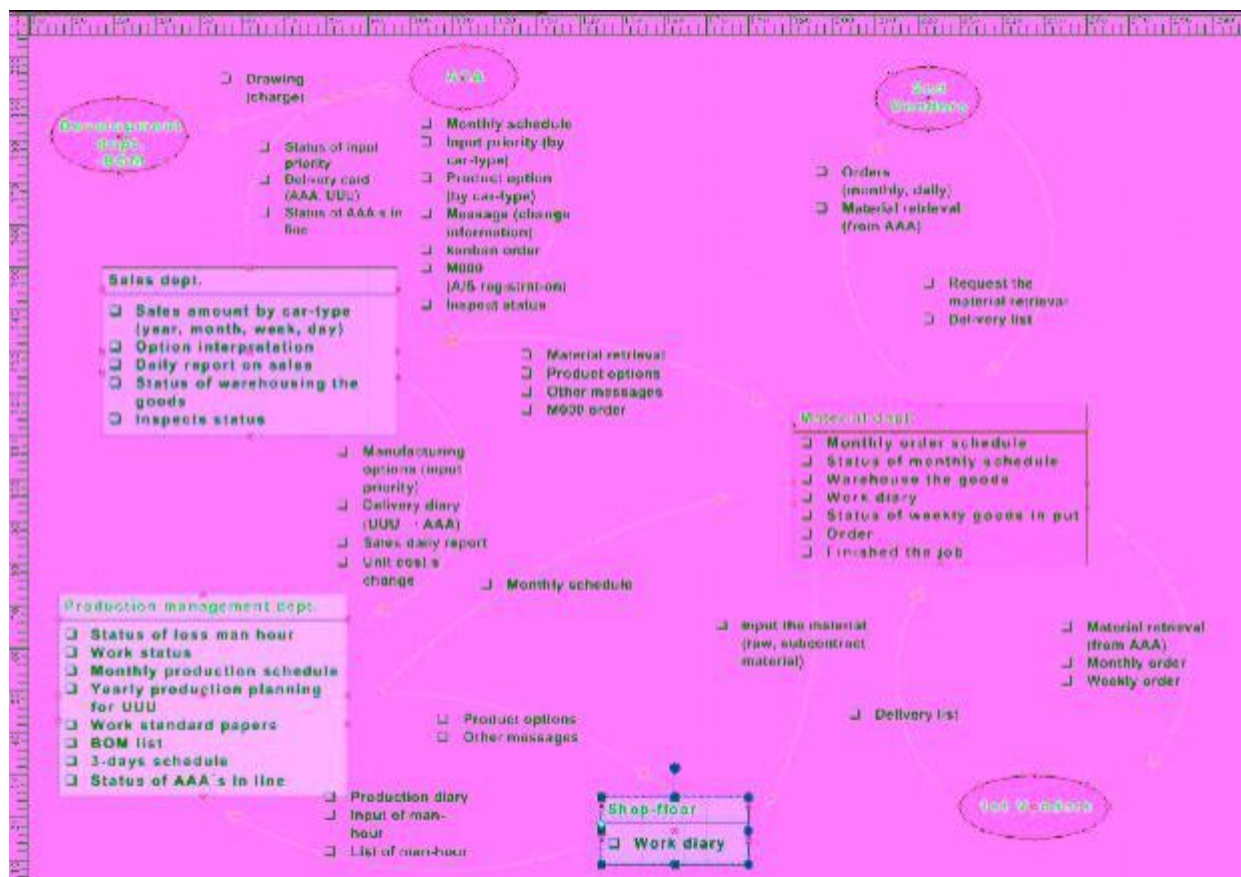

### 3. SYSTEM ANALYSIS

#### 3.1 Information flow within procurement process

We analyzed a delivery process that the company AAA transmits to the 1st vendors' monthly production plan, the input sequence of the final assembly line and specification reports. The sales part of the 1st vendor gets these order information through a VAN system and passes those information on the other part, such as production control and procurement department of the company. The operation manager makes a monthly production plan from AAA's monthly plan and a 3-days production schedule on the basis of AAA's sequence

information and specification report. Currently, the monthly plan and 3-days schedule made by the operation manager are notified to related divisions (purchase section, production section, and sales section) and related 2nd vendors in a document. The purchasing manager calculates net requirement of each part on the basis of BOM (Bill of Material) and inventory records of the parts. And then purchasing orders are delivered to related 2nd vendors.

The raw materials are requested and released to produce bus roof by 3-days production schedule. The released materials are transmitted to the process line, and then the results of production are recorded in job card and work diary to the end of manufacturing. A delivery man of company UUU or DDD distributes completed parts with delivery card to the assembly line of company AAA according to a daily delivery schedule. The sales manager checks the daily delivery results from AAA's VAN system. Even though business processes of two companies UUU and DDD are slightly different each other, the principal business processes of two companies are almost same. <Figure 2> shows the work flow of two companies.

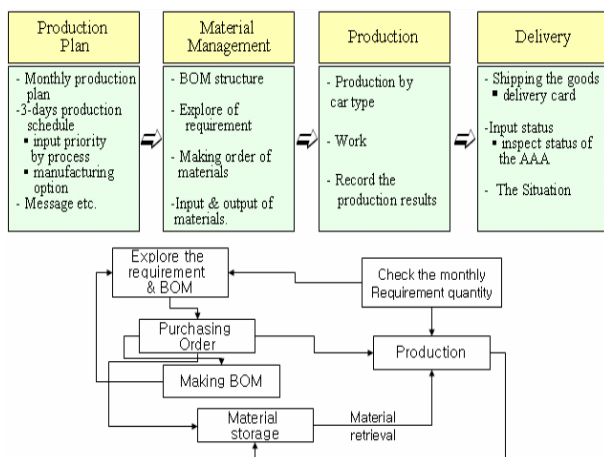

#### 3.2 Analysis of the work flow

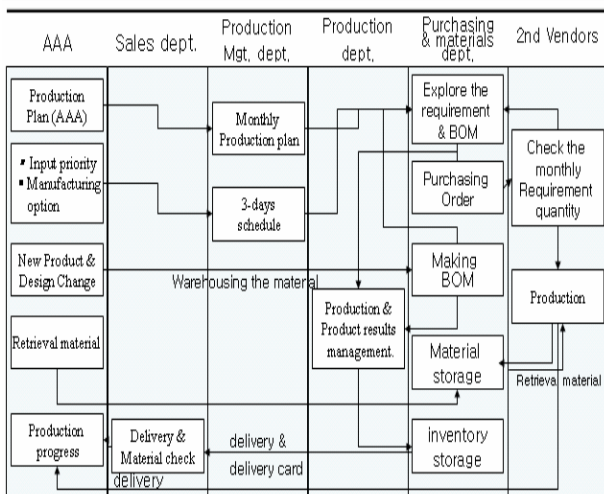

The sales department receives the monthly production plan, the input sequence of each assembly line, manufacturing specification and the other special

messages from AAA's VAN system and distributes to the department of production management and purchasing department. The AS-IS analysis about information flow between departments of the 1st vendors was accomplished for main four departments (sales, production, purchasing

materials and production management). The sales department supplies materials, which are received from AAA, to the production department. The department delivers the completed parts into the corresponding assembly line of company AAA and checks the production line stands of AAA and delivery status etc. The department of production management makes each production plan (monthly and 3 daily). The purchasing department calculates the material requirements by a monthly and 3-days schedule and makes an order to the 1st and 2nd vendors. <Figure 3> summarizes the work flow related with production management and material management. The whole business flows including the 2nd vendors are shown in <Figure 4>.

<Figure 3> Work flow of production management and material handling

<Figure 4> Work flow for 1st vendors and their divisions, AAA company and 2nd vendors.

## 4. SYSTEM DESIGN

### 4.1 Conceptual Design of an e-SCM [7]

The system was designed based on client/server structure which is a typical structure of a web-based system. The conceptual framework of the system is shown in <Figure 5>. The figure shows that the system consists of a web

server, a DB server, and three functional modules such as production controller, sales manager, and purchasing & material manager. The users of the 1st and 2nd vendors access to web-server through Internet and the web-server makes connection to an appropriate module.

The second vendors can check out the net requirement and current inventory records from the web page of the 1st vendor any time, and decide how many or what items they should deliver. To do this, the 1st and 2nd vendors must agree with the proper inventory level or average inventory level for each part. That is, vendor managed of the 1st vendors.

<Figure 5> A Conceptual framework of the e-SCM system.

### 4.2 Design of Database

As DB is indispensable for developing the e-SCM system, it has to be designed for contents of easy access, correction and update[6]. DB includes valuable and various data about primary data of manufacturing item, parts, sub vendors, drawing data, inventory records, production schedule, bill of material information and production or delivery data. DB takes different effect for performance by times of access. Therefore, DB, in this study is designed with divided table by size of data and times of access to table with planning system. A relational database concept was used to design the DB which maintains data needed in the system.

<Figure 6> shows the relations with some tables and the table ASSY which stores primary data about finished goods. ASSY table includes basic information about finished part such as product ID code, price, car-type etc. ASSY\_INV maintains product ID code and on-hand inventory of finished item at company AAA and the 1st vendor. ASSY\_SKETCH table consists of the name and code of drawing, the version of drawing and the file name of drawing etc.

Part DB includes various kinds of primary information such as drawing data, inventory information and manufacturing style etc. Since the frequency of access varies according to kinds of data, DB table was partitioned by the frequency and size of data. PART DB

## 5. CONCLUSION

This paper is a case study to develop an e-SCM system to control a part of procurement supply chain of a commercial vehicle company. To do this, we analyzed the business process, information flow, and material flow among companies in the selected chain. And then, we designed the e-SCM system based on the results of the analysis. We designed the system to be developed based on web technology. The monthly plan and 3-days schedule of the 1st vendor will be made using monthly plan and input sequence of AAA. The second vendors can check out the net requirement and current inventory records of parts through the web page of the 1st vendor any time, and decide how many or what items they have to deliver. That is, vendor managed inventory(VMI) concept was applied to control inventory between the 1st and 2nd vendors.

## ACKNOWLEDGEMENT

This research was supported by the Program for the Training of Graduate Students in Regional Innovation

which was conducted by the Ministry of Commerce, Industry and Energy of the Korean Government.

# Development Stages of Supply Chain Management in E-Business Environment

Jeongwook Choi

Business School, Kookmin University, Seoul, 136-702, Korea  
jwchoi@kookmin.ac.kr

## ABSTRACT

The emergence of electronic Business, or e-Business, has changed the operations and contents of traditional supply chain management or SCM. e-Business not only makes the operation of SCM more effective, but also plays the role of a major driving force to induce the development of new features of SCM by destroying the rules and orders that once governed and controlled SCM in the past. Based on this understanding, this paper focuses on studying how e-Business has changed the ways SCM creates added values in the following areas: the nature and contents, steps, fields and structures of value chains comprising SCM. To this end, this paper first divides overall development of supply chains into three stages. Then, detailed analysis of the features, development processes and characters of each development stage shall be discussed to identify the factors driving the changes. In addition, the types of developments shall be identified and discussed.

**Keywords:** e-Business, Supply Chain Management, Development Stages

## 1. INTRODUCTION

How does the e-Business change Supply Chain Management? e-Business does not simply enable customers to purchase goods and services over the Internet. The new form of Business backed by the Internet technology has profoundly changed the structure and meaning of supply chains. In this regard, this paper will look at how e-Business influences supply chains and how the influence actually changes the shape of overall supply chains.

Researches on supply chains have uncovered a number of diversified findings. Despite the diversified studies on supply chains, few studies have been performed on how e-Business changes supply chains, what would be root causes and driving forces to the change, and what it would look like after the change is done. This paper aims at establishing the development theory of supply chain evolution according to e-Business environment. In addition, two main themes are touched upon in this paper. e-Business based on the Internet platform changes supply chains. In this regard, this paper firstly classifies the structures of development stages leading to the evolution of supply chains in order to study the features and characteristics of changes by development stage. Secondly, this paper will look at the types of changes and the factors causing such changes.

## 2. STAGES OF SCM DEVELOPMENT UNDER E-BUSINESS ENVIRONMENT

The advancement of e-Business has a profound impact on the development of supply chains. What are the specific impacts of e-Business on supply chain management? To answer this question, this paper looks at the influence of e-Business (or the advance of e-Business) on the development of supply chains by dividing the developments into three stages.

### 2.1. 1<sup>st</sup> Stage – Phase of Continuous Improvement

In principle, all developments start with a stage to improve parts which are currently unsatisfactory. Improvement refers to activities to analyze current status to come up with a better condition. Thus, an improvement is inevitably found on the continuity of existing conditions. Familiar examples of such improvements are: How can we minimize the level of inventory?; How can we accelerate the delivery of demand to customers?; How can we harmonize and match demand and supply?; And how can we enable members of supply chains to share accurate information on a real time basis and to utilize needed information in a timely manner? As the examples indicate, the stage of improvement is to address such issues as bullwhip effect, excessive inventory, mismatches between demand and supply, delayed response to customers, and silo mentality of functional areas. Such improvement is motivated by current unsatisfactory status within an organization and is performed to resolve the issues by utilizing new environment and methodologies supported by e-Business. The phase of continuous improvement can ultimately be defined as the process of eliminating wastes and non-value added works in supply chain operation. In other words, the 1<sup>st</sup> development stage is the process of achieving maximum efficiencies and effectiveness to operate supply chains.

Examples of continuous improvement stage such as to eliminate errors and redundancies in supply chain operations, to lower inventory levels, to shorten product development cycle, to eliminate bullwhip effect and so on can be found in many companies. All components of supply chains share information to maintain optimal level of inventory and to support the fastest logistic movement; and users are able to utilize analytic information required for the operations of supply chains at the time they want.

[Figure 1 : Proportional Relationship between benefit and cost of information]

Traditionally, there has been a trade-off relationship between cost and effect of information. For instance, accurate information would have been shared through all supply chain members if value added networks or VAN was used to connect all supply chain members but this had not been realized because the costs were huge. However, the advancement of the Internet enabled automatic linkage of all members of supply chains to allow the members to exchange real-time information without accompanying large investment, as was the case in the past. At the same time, the accuracy and timeliness of information have improved greatly.

## 2.2. 2<sup>nd</sup> Stage – Phase of Structural Change

Customers have exerted to achieve what they wanted from traditional supply chains. The emergence of e-Business environment, however, has lifted the boundaries of thoughts of customers. In other words, once unthinkable in the traditional supply chains has turned into realities. For example, customers have become able to directly purchase goods from manufacturers without going through complicated distribution transactions. A company can act with another company located in a remote region as if they are one. These changes are not attributable to the operational efficiency intrinsic to supply chains. Rather, new environmental developments due to the emergence of e-Business have turned things that were once regarded difficult or impossible into possible features. These are not continuous or evolutionary changes from the past but disruptive or discontinuous ones. When faced with the limitations of improvement efforts that have been achieved in the 1<sup>st</sup> stage – phase of continuous improvement, companies start to recognize that the gradual improvements can no longer be used for development. Then they start to seek new ways of development or evolution. Sometimes, external shocks may transform on-going improvement activities into new types of activities or a new framework that are discontinuous from the past and out of the track of improvement projections. Both the cases of discontinuous improvement symbolize the 2<sup>nd</sup> stage – phase of structural change. In the stage of structural change, you can find:

### (1) Disintermediation

e-Business provides an environment in which customers can directly interact with producers. In other words, customer and producers do direct transactions via the Internet without utilizing traditional distribution channels.

[Figure 2 : Disintermediation]

### (2) Virtual Supply Chain

Virtual supply chain refers to a system in which physically separated unit companies with unique core competencies collaborate to achieve a single target. A good example would be a collaborative shoe making network comprised of the followings: a German shoe producer which owns brand; an Italian company performs shoe designs; a Korean company takes charge of producing; a Singaporean company carries out global logistics; and a U.S. company provides customer services. As this example shows, a virtual supply network is a system in which a number of different companies gather together without regarding the limitations of time and space to act as a one entity.

[Figure 3 : Virtual Supply Chain]

### (3) e-Marketplace

Traditional relationship between suppliers and manufacturer was based on almost-fixed one-to-one ties between a supplier and a manufacturer. e-Marketplace changed ways of doing businesses of buyers and suppliers and allows them to overcome the limitations of traditional relationships by creating a single cyber marketplace where multiple suppliers do transactions with multiple buyers.

To sum up structural changes occurring in the 2<sup>nd</sup> stage: Collaboration of supply chain members has been pursued to reduce the total cycle time from customers to producers and to share information in a more efficient manner. These efforts have been discussed in the 1<sup>st</sup> stage of continuous improvement. In the 2<sup>nd</sup> stage of structural change, however, the focus of such efforts has shifted from the efficiency of a supply chain to the change of overall structure of a supply chain. In this stage, supply chains undergo discontinuous changes, not gradual improvements as are the case in the 1<sup>st</sup> stage. In this regards, we call changes occurring in this stage “structural changes” to reflect the fact that the overall framework of supply chains are subject to change.

Disintermediation, virtual supply networks or e-marketplaces are understood as types of such structural changes.

[Figure 4 : e-Marketplace]

Major driving force leading to the structural changes in the second stage would be the destruction of trade-off relationship between the richness and the reach of information where richness of information means that information contains sufficient contents to enable decision-making and reach of information means the scope within which information can be shared. For more details about the reach and richness, see Evans and Wurster (1999).

### 2.3. 3<sup>rd</sup> Stage – Phase of Convergence/Chaos

If the rate of structural change exceeds a certain level, such change becomes no longer controllable and starts to create spontaneous changes. This paper defines the 3<sup>rd</sup> stage as the phase of convergence/chaos changes. In this stage, the traditional definition of supply chains becomes meaningless and chaotic revolution starts to prevail. For the purpose of this paper, the chaotic revolution is defined to be a stage in which new types of converged supply chains emerge and all industries are combined with other industries, followed by the creation of new types of industries.

Values once provided by a single industry for customers come to lose their competitiveness. Thus, industries start to converge with new industries to overcome the borders of traditional industries and to provide comprehensive values to customers. For instance, on-line stock trading is a financial industry combined with IT industry. Similar examples are: mega-markets supporting purchasers to buy various products of various industries in one marketplace; integrated and converged financial service markets which have seen segmented among banks, non-banking financial institutions, insurance companies, credit union; and also the crossover competition and cooperation between credit card companies and cell phone carriers caused by the addition of credit card functional service provided by cell phone terminals. These cases manifest disappearing distinctions between traditional industries.

The speed and severity of such changes further move supply chains forward to have more and more new features. Customers come to demand all their requirements to be met at one place and the demarcations among traditional industries become

indistinct. Primary activities and supporting activities of value chains become no longer separated and the boundaries dividing industries start to disappear. Thus, the one and only yard stick of supply chain is: which supply chain delivers goods or services to customers with the highest level of customer satisfaction? When these are considered, major competitiveness of traditional supply chains, the capability of creating unique values, may become meaningless.

[Figure 5 : Converged Supply Chains]

As the figure shows, industries A, B, and C secure their own customers. These supply chains, however, start to be integrated to form a new network by integrating what customers want. As a result, supply chains by industry and by companies become no longer meaningful and, ultimately, a combination of values meeting customer needs would win the competition.

The major force driving this change is the transition of information ownership from producers to consumers. Up until now, a number of people have remarked that the paradigm has shifted from a producer's market to a consumers' market. Nevertheless, industry paradigms remained the same and the new market was not a truly consumer-oriented market although consumers could exercise more influence than before. The information revolution induced by e-Business, however, allows consumers to hold power of having complete and integrated information, which in turn enables them to select goods and industries that they want, to combine or transform producers as they want. Here, such change is defined to be chaos because it is not clear which direction the change will take. The only clear thing is that a converged and integrated supply chain which ensures the maximum customer satisfaction will become a winner in the competition.

### 3. SCM UNDER E-BUSINESS – TYPES AND FEATURES OF DEVELOPMENT STAGES

Previous sections have viewed how traditional supply chains change under e-Business environment. This section will analyze the types and features of such changes. The table below briefly touches upon the features of each development stages.

[Table 1 : The features and characteristics of the stages in supply chain]

Development Stage	1 <sup>st</sup> stage	2 <sup>nd</sup> stage	3 <sup>rd</sup> stage
Characteristics	Continuous and gradual improvement	Structural and discontinuous change	Chaotic and unpredictable convergence
Features	Serial supply chain	Parallel and network supply chain	Integrated and converged supply chain
Change drivers	Destruction of trade-off relationship between cost and effect of information	Destruction of trade-off relationship between reach and richness of information	Transition of Information ownership from producers to consumers
Performance measures	Effectiveness and efficiency of supply chain operation	Optimal structure of supply chain design	Maximum customer satisfaction
Change pattern Predictability	High	Medium	Low

As is shown in the above table, the first stage focuses on enhancing efficiency and effectiveness of operations and decreasing non-value added activities in supply chain operations. Such development has been available because the cost of managing supply chain information is not costly as before. Because of the continuous nature of development, it is possible to predict the development of overall operations of supply chains and the level of improvement in terms of effectiveness and efficiency. Unfortunately, however, once substantial changes have been made through the first stage of continuous improvement, it becomes very difficult to gain more desirable impact although new efforts are exercised. In other words, it becomes clear that this kind of continuous improvement almost reaches the peak of the first stage's ideal status within the current structure of supply chain. Thus, it becomes inevitable to change the structure of supply chains - external factors, not internal factors - in order to create new stage of developments. Then it begins to initiate efforts to change the supply chain environment given. In the past, most external factors were given, so it was almost impossible to change. However, the emergence of e-Business features and the application of such features opened the ways for the structural changes of supply chains. In this second stage of structural changes, unlike in the first stage, supply chains started to be re-configured, and develop more innovative structural changes.

While the first stage focused on the continuous and gradual improvement of the ways of supply chain operations, the second stage has concentrated on discontinuous development in a way to innovate overall structure of supply chains. The second stage of structural change has re-designed and re-constructed supply chains in an innovative way by utilizing the features of the Internet environment. For instance, during the second stage of development, innovative change of performing direct linkage between producers and consumers emerged, if needed, by destroying the intermediary steps linking the two parties. In other words, the second stage was about re-structuring of operations of companies and supply chains in an

innovative manner through the destruction of the previous formats. In summary, full utilization of e-Business features in the Internet environment for re-designing and re-organizing new supply chains characterizes the second development stage.

Although innovative re-structuring change has been prevalent in the second stage, competition is still limited within supply chains performing similar businesses or within similar industries. As a result, winning a competition in the second stage means a success among companies or supply chains performing similar businesses or within the same industry. Further development of e-Business technologies in the third stage of convergence and chaos, however, accelerates the advance and establishment of an era of consumers. In the new era, consumers start to ignore the boundaries embedded in the traditional industries and supply chains and require the type of a company or a supply chain that best fits their needs. In this case, however, the competitiveness of supply chains improved through innovative re-structuring activities in the second stage would be meaningless unless customers select such supply chains. Thus, consumers drive the convergence and integration of industries as they want. In other words, the convergence and integration of industries are made in a way to maximize customer satisfaction. In addition, as the development is led by customers, it is very chaotic to predict the development directions in the third stage. Thus, the convergence between companies, supply chains or industries would render a brand-new industry or supply chain.

#### 4. CONCLUSION

This paper reviews how the emergence of e-Business changes supply chains. In this regard, features of development stages are classified, actual cases of the features are identified, driving forces of each stage are studied and analyzed, and the types of possible evolutions are suggested.

e-Business first acts as a driving force for improving current status, supports information sharing on a

real-time basis, and allows paperless management through electronic document exchanges. As a result, e-Business makes supply chains more effective and efficient as a whole.

Further advancement in e-Business destroys the trade-off relationship between richness and reach of information. This causes a brand-new development happen, leading to direct linkage between customers and producers, emergence of virtual enterprises, and a new-marketplace utilizing cyber space. In this stage, e-Business stops being a stimulus to facilitate supply chain's operational efficiency but acts as an innovative driver for changing the structure and shape of overall supply chains. One-step further advancement in e-Business blurs the demarcation lines among industries and leads supply chains into the stage of convergence and chaos full of disrupted scope and contents of competition.

The development stages are triggered by unique forces driving changes in each stage and the speed of change is dependent upon the severity of the drivers. The progress of development is not gradual; rather, it shows a number of development types.

Further researches into the characteristics of each development stage are required along with the analyses of actual cases to be observed in the industries. By doing so, models representing each development stage and more in-depth and diversified analyses of actual progresses of each stage would be carried out to track actual developments and realization of changes.

### ABSTRACT

In this paper, we consider the e-booking control problem which includes optimal pricing and capacity allocation. In pricing model, customers may refuse bookings based on their willingness to pay the quoted price. Since customer behavior and characteristics are highly varying and not known in advance, we develop a stochastic pricing model which tracks customer behavior as well as the arrival process to maximize profit. For the multi-period capacity allocation of e-booking control problem, we present a two-stage stochastic mixed integer programming model and a heuristic algorithm. The solution to the model is found by maximizing the expected profit over the possible control decisions under the uncertainty of shipping capacity. Finally, we give numerical experiments demonstrate the efficiency of the algorithm.

**Keywords:** e-booking control, container shipping industry, mathematical programming

### 1. INTRODUCTION

Alliances and partnerships are prevailing characteristics of the container shipping industry. A brutally competitive environment, low freight rates, and the need for carriers to increase their revenue have led to joint carrier operations. Carriers have to band together in operating alliances with the objectives of improving capacity utilization and more service flexibility. Unfortunately, this consolidation has not resulted in upward pressure on shipping rates, nor has it increased profitability for the carriers involved. The high cost of capital equipment and low rates of return that characterize container shipping compel carriers seek out every opportunity to improve their own with respect to operational efficiency and performance (see [3], [5]).

Effective booking control is a key to improved revenues and reduced container shipping costs and it has become more important when the container shipping industry has widely adopted information technologies. E-booking service supports e-business strategy for container shipping industry, which aims to make business processes easier and more cost efficient. As a part of sea cargo e-commerce strategy, web-based e-booking system enables the customer to electronically book shipments and to channel other shipment requirements to the carrier, such as cargo collection, delivery requests, and information required for customs clearance. In general, e-bookings may be made up to 30 days in advance. The customers can specify the number and type of containers needed, and service time windows at the origin and destination locations. Minimally, the time window information must include the earliest time containers may be loaded at the origin, and the latest time containers should be delivered to the destination. The objective of e-booking service is to help customers enjoy the competitive advantage of the Internet and provide an efficient, flexible and fast way of doing business. Customer Service staff can also help customers with more complicated bookings that require special expertise.

The whole industry-shippers, forwarders, carriers and consignees-benefit from minimizing or eliminating duplicate data entry. It makes the shipment process more transparent and improves the accountability of service provide. This means that the monthly freight schedule booking process can be done by pressing one button. A new e-business strategy will improve customer service and efficiency for both carriers and their customers. This move to a more efficient and effective way of making cargo booking is an important part of operational level service route planning in container shipping industry.

To obtain service, customers first check the price quote for a given origin-destination service in e-booking website, and then subsequently make bookings under the quote. With the exception of certain ancillary charges, the carrier charges the customer a fixed price for transportation, and pays the transportation service providers directly out of this fee. Therefore, it is in the carrier's interest to minimize the transportation costs for most shipments. However, there must be a level of "reasonableness" in transit times, and some customers may be willing to pay a premium for faster service.

In this paper, we consider the e-booking control problem in the container shipping industry, which includes pricing and capacity allocation. The pricing and revenue management problem is formulated as nonlinear programming in which some parameters obtained from stochastic marked point process. The capacity allocation problem is formulated as two-stage stochastic mixed integer programming model which accounts for total profit in multi-period and constraints of limited shipping capacity. Efficient algorithms for the models and numerical experiments are proposed at last. The rest of the paper is organized as follows. The problem formulation and algorithm are described in Section 2. Empirical results are given in Section 3. We conclude the paper in Section 4.

## 2. PROBLEM FORMULATION

### 2.1. Pricing and Revenue Management

Consider an e-booking system for an ocean liner operator. Cargo bookings arrive at the system according to a compound Poisson process  $\{X(t)\}_{t \geq 0}$ . Its jump times  $T_1, T_2, T_3, \dots$  form a Poisson process with rate  $\lambda > 0$ , and the jump magnitudes  $Y_1, Y_2, Y_3, \dots$  are *i.i.d.* random variables with Pareto distribution. The Pareto principle states that a large income stems from a very small number of customers. It is reasonable to assume that the freight volume of a booking follows Pareto distribution (see [1]). The Pareto probability density function with shape parameter  $a > 1$  and scale parameter  $b > 0$  is defined as

$$f(x) = \frac{ab^a}{x^{a+1}}, \text{ for } x \geq b \quad (1)$$

Figure 1 illustrates the Pareto probability density function for different values of shape  $a$  and scale  $b=40$ .

Figure 1. Pareto probability density function

When the quoted price is  $p$ , an arrival customer may accept or reject the price. Let  $\xi$  be the binary random variable, i.e.,  $\xi=1$  if the arrival customer accepts the quoted price;  $\xi=0$ , otherwise. We assume that the random variable  $\xi$  is independent of booking arrival process and the probability that an arriving customer accepts the quoted price  $p$  is a decreasing and differentiable function of  $p$ . The probability is chosen as

$$g(p) = 1 - \left(\frac{p}{\theta}\right)^\delta, \text{ for } p \leq \theta \quad (2)$$

where  $\delta$  and  $\theta$  are constants. By varying the parameter  $\delta$ , we can make the willingness as elastic as desired. The lower the value of parameter  $\delta$ , the more willing are customers to book under the quoted price. Figure 2 shows the function  $g(p)$  for different values of parameter  $\delta$  and  $\theta=10$ . The total profit in time  $t$  is:

$$Z(t) = \sum_{i=1}^{\infty} Y_i 1_{0 \leq T_i \leq t} p 1_{\xi=1} \quad (3)$$

Figure 2. Probability of acceptance under quoted price  $p$

Let total available capacity is  $C$ . Then we formulate the pricing and revenue management problem for single cargo type and single period as following nonlinear programming (M1):

$$\text{Maximize } EZ(t) = E \sum_{i=1}^{\infty} Y_i 1_{0 \leq T_i \leq t} p 1_{\xi=1} \quad (4)$$

subject to

$$E \sum_{i=1}^{\infty} Y_i 1_{0 \leq T_i \leq t} 1_{\xi=1} \leq C \quad (5)$$

Obviously, stochastic process  $\{Z(t)\}_{t \geq 0}$  is a marked point process and the expectation of  $Z(t)$  is (for details of marked point process, see [2]):

$$\begin{aligned} EZ(t) &= EY_1 \cdot \lambda t p \cdot P \xi = 1 \\ &= \frac{ab\lambda t p}{a-1} \left[1 - \left(\frac{p}{\theta}\right)^\delta\right] \end{aligned} \quad (6)$$

Similarly,

$$E \sum_{i=1}^{\infty} Y_i 1_{0 \leq T_i \leq t} 1_{\xi=1} = \frac{ab\lambda t}{a-1} \left[1 - \left(\frac{p}{\theta}\right)^\delta\right] \quad (7)$$

In the following theorem, we give the optimal of above nonlinear programming.

**Theorem 2.1.** The optimal solution of the nonlinear programming (M1) is

$$p^* = \max(\hat{p}, \bar{p}) \quad (8)$$

where

$$\hat{p} = \frac{\theta}{(\delta+1)^{1/\delta}}, \text{ and } \bar{p} = \theta \left[1 - \frac{c(a-1)}{ab\lambda t}\right]^{1/\delta}.$$

Proof. Let

$$\eta_1(p) = \frac{ab\lambda t p}{a-1} \left[1 - \left(\frac{p}{\theta}\right)^\delta\right], \quad \eta_2(p) = \frac{ab\lambda t}{a-1} \left[1 - \left(\frac{p}{\theta}\right)^\delta\right],$$

then we easily verify that the function  $\eta_1(p)$  is concave in  $(0, +\infty)$  and it takes maximum at point:

$$\hat{p} = \frac{\theta}{(\delta+1)^{1/\delta}} \quad (9)$$

On the other hand, the function  $\eta_2(p)$  is decreasing in  $(0, \theta)$  and it takes zero at point:

$$\bar{p} = \theta \left[1 - \frac{c(a-1)}{ab\lambda t}\right]^{1/\delta} \quad (10)$$

Therefore, the optimal solution of non-linear programming (M1) is  $p^* = \max(\hat{p}, \bar{p})$ .

## 2.2. Capacity Allocation

We assume that the capacity allocation decisions (for the entire planning horizon) have to be made, with only some knowledge of future scenarios of parameters. The overall objective is to determine a capacity allocation plan, such that the sum of each expected profit is maximized. To incorporate the uncertainty in the parameters, we assume that these parameters can be realized as one of  $S$  scenarios. The probability of scenario  $s$  will be denoted by  $p^s$ .

Before formally stating the problem, we introduce some notation:

### Index Sets

$\tilde{T}$ : set of time periods  $\{1, 2, \dots, t, \dots, T\}$ .

$\tilde{K}_t$ : set of all cargoes received in period  $t$ , i.e.

$\tilde{K}_t = \{1, 2, \dots, k, \dots, K\}$ .

$\tilde{S}$ : set of all scenarios  $\{1, 2, \dots, s, \dots, S\}$ .

### Deterministic Parameters

$r_{tkd}$ : per volume profit of cargo  $k$  which is received in period  $t$  and delivered in period  $d$ . It can be interpreted as the per volume net profit of cargo  $k$ , i.e., per volume profit of cargo  $k$  minus its per volume inventory cost.

$\tau_k$ : due date of cargo  $k$ . Each cargo has its due date requested by shipper in its booking status.

$v_{tk\tau_k}$ : the volume of cargo  $k$  received in period  $t$  ready for delivery before its due date  $\tau_k$ .

$w_{tk\tau_k}$ : weight of cargo  $k$  received in period  $t$  ready for delivery before its due date  $\tau_k$ .

### Random Data

$V_t^s$ : total available volume capacity in period  $t$  under scenario  $s$ .

$W_t^s$ : maximum allowable weight capacity in period  $t$  under scenario  $s$ .

$q_{d1}^s$ : overage cost per unit overage of volume capacity in period  $d$  under scenario  $s$ .

$q_{d2}^s$ : shortage cost per unit short of volume capacity in period  $d$  under scenario  $s$ .

$q_{d3}^s$ : overage cost per unit overage of weight capacity in period  $d$  under scenario  $s$ .

$q_{d4}^s$ : shortage cost per unit short of weight capacity in period  $d$  under scenario  $s$ .

### Decision Variables

$x_{tkd}$ : binary variable, i.e.,  $x_{tkd} = 1$  if cargo  $k$  is received in period  $t$  and is ready for delivery in period  $d$  before its due date  $\tau_k$ , 0, otherwise.

$y_{d1}$ : amount of overage of available volume capacity in period  $d$ .

$y_{d2}$ : amount of shortage of available volume capacity in period  $d$ .

$y_{d3}$ : amount of overage of allowable weight capacity in period  $d$ .

$y_{d4}$ : amount of shortage of allowable weight capacity in period  $d$ .

The multi-period capacity allocation problem can then be formulated as following two-stage stochastic mixed integer programming model (M2):

$$\text{Maximize } z = \sum_{t=1}^T \sum_{k \in \tilde{K}_t} \sum_{d=t}^{\tau_k} v_{tk\tau_k} r_{tkd} x_{tkd} - \sum_{s=1}^S p^s Q^s(x) \quad (11)$$

subject to

$$\sum_{d=t}^{\tau_k} x_{tkd} \leq 1 \quad \forall t \in \tilde{T}, k \in \tilde{K}_t \quad (12)$$

$$x_{tkd} \in \{0, 1\}, \quad (13)$$

$$\text{For } \forall t \in \tilde{T}, k \in \tilde{K}_t, d \in \{t+1, \dots, \tau_k\},$$

where for all  $s$ ,

$$Q^s(x) = \text{Minimize } \sum_{d=1}^T \sum_{i=1}^4 q_{di}^s y_{di} \quad (14)$$

subject to

$$y_{d1} - y_{d2} = V_d^s - \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} v_{tk\tau_k} x_{tkd} \quad \forall d \in \tilde{T} \quad (15)$$

$$y_{d3} - y_{d4} = W_d^s - \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} w_{tk\tau_k} x_{tkd} \quad \forall d \in \tilde{T} \quad (16)$$

where all  $y_{di}$  are non-negative for  $d \in \tilde{T}$ ,  $i=1,2,3,4$ .

Because all random variables in (M2) are discretely distributed, and their joint distribution has a finite number of realizations, (M2) can be rewritten as the following large-scale mixed integer programming model (M3):

$$\text{Maximize } z = \sum_{t=1}^T \sum_{k \in \tilde{K}_t} \sum_{d=t}^{\tau_k} v_{tk\tau_k} r_{tkd} x_{tkd} - \sum_{s=1}^S p^s \sum_{d=1}^T \sum_{i=1}^4 q_{di}^s y_{di} \quad (17)$$

subject to

$$\sum_{d=t}^{\tau_k} x_{tkd} \leq 1 \quad \forall t \in \tilde{T}, k \in \tilde{K}_t, \quad (18)$$

$$y_{d1}^s - y_{d2}^s = V_d^s - \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} v_{tk\tau_k} x_{tkd}, \quad (19)$$

$$\text{for } \forall \notin \tilde{T}, j \in \tilde{J}, s \in \tilde{S}$$

$$y_{d3}^s - y_{d4}^s = W_d^s - \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} w_{tk\tau_k} x_{tkd}, \quad (20)$$

$$\text{for } \forall \notin \tilde{T}, s \in \tilde{S}$$

where  $x_{tkd} \in \{0,1\}$ , for  $\forall t \in \tilde{T}, k \in \tilde{K}_t$ ,  
 $d \in \{t+1, \tau_k\}$  and all  $y_{di}^s$  are non-negative for  
 $s \in \tilde{S}, d \in \tilde{T}, i = 1, 2, 3, 4$ .

A common attitude in solving NP-hard combinatorial optimization problems (see [4]) is to not insist on optimality but dedicate research efforts to designing fast and high quality approximation methods. A greedy algorithm is chosen for solve the problem (M3). Its robust and implicit enumerative character ensures to achieve the optimal solution or a near optimal solution. In cases like this we can sacrifice the guarantee of optimality that is provided by it in favor of getting a reasonable answer quickly.

Let  $E_d = \min\{E_d^s : s \in \tilde{S}\}$ ,  $V_d = \min\{V_d^s : s \in \tilde{S}\}$ ,  
 $W_d = \min\{W_d^s : s \in \tilde{S}\}$ ,  $\bar{v}_{tk\tau_k}^d = v_{tk\tau_k} / V_d$ ,  
 $\bar{w}_{tk\tau_k}^d = w_{tk\tau_k} / W_d$ . Then, we get a binary integer programming as follows (M4):

$$\text{Maximize } z = \sum_{t=1}^T \sum_{k \in \tilde{K}_t} \sum_{d=t}^{\tau_k} v_{tk\tau_k} r_{tkd} x_{tkd} \quad (21)$$

subject to

$$\sum_{d=t}^{\tau_k} x_{tkd} \leq 1 \quad \forall \in \tilde{T}, k \in \tilde{K}_t \quad (22)$$

$$\sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} \bar{v}_{tk\tau_k}^d x_{tkd} \leq 1 \quad \forall \in d \in \tilde{T} \quad (23)$$

$$\sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} \bar{w}_{tk\tau_k}^d x_{tkd} \leq 1 \quad \forall \in d \in \tilde{T} \quad (24)$$

where  $x_{tkd} \in \{0,1\}$ ,  $d \in \{t+1, \tau_k\}$ ,  $\forall \in \tilde{T}$ ,  
 $k \in \tilde{K}_t$ ,

Toyoda's heuristic for the Multi-Dimensional Knapsack Problem (MDKP) (see [6]) starts with no items (or all  $x$ 's being zero), and adds one item at a time iteratively as long as the solution is feasible. Following his approach, we propose a heuristic algorithm EBHA that provides a near-optimal solution to (M2) by means of concepts such as penalty vector and effective gradient introduced in [6].

The heuristic algorithm for the mixed integer

programming (M3) is presented as follows.

#### Algorithm EBHA:

**Step 1:** Initialization.

**Step 1.1:** Let  $z \leftarrow 0$ ,  $\hat{z} \leftarrow 0$ ,  $x_{tkd} \leftarrow 0$ ,  $\hat{x}_{tkd} \leftarrow 0$ .

**Step 1.2:** Let  $K_U \leftarrow \emptyset$ , where  $K_U$  is the set of accepted items.

**Step 1.3:** Assign all items to  $K_D = K - K_U$ , where  $K_D$  is the set of items not in  $K_U$  and  $K = \{k : k \in \tilde{K}_t, t \in \tilde{T}\}$ .

**Step 1.4:** Let  $A_U^d \leftarrow (0, 0)$ , where  $A_U^d$  is the total quantity vector of accepted items in period  $d$ .

**Step 2:** Let  $K_C \leftarrow \{k : k \in K_D, \exists d \leq \tau_k \text{ s.t.}$

$(\bar{v}_{tk\tau_k}^d, \bar{w}_{tk\tau_k}^d) \leq (1,1) - A_U^{dj_k}\}$ , where  $K_C$  is the set of candidate items.

**Step 3:** Check  $K_C$ . If  $K_C$  is empty, goto **Step 7**.

Otherwise, proceed to the next step.

**Step 4:** Let  $\bar{K}_C = \{k \in K_C, k \in K_D\}$ ,

$(\bar{v}_{tk\tau_k}^d, \bar{w}_{tk\tau_k}^d) \leq (1,1) - A_U^d\}$ .

**Step 4.1:** If  $A_U^d$  is a zero vector, then we set

$$G_{kd} \leftarrow \frac{\sqrt{2} v_{tk\tau_k} r_{tkd}}{\bar{v}_{tk\tau_k}^d + \bar{w}_{tk\tau_k}^d}, \text{ for } (k,d) \in \bar{K}_C$$

**Step 4.2:** Otherwise, let  $K_U^d = \{k' : k' \in K_U, x_{tk'd} = 1\}$ , for  $(k,d) \in \bar{K}_C$ , we set

$$G_{kd} \leftarrow \frac{v_{tk\tau_k} r_{tkd} \sqrt{(\sum_{k' \in K_U^d} \bar{v}_{tk'\tau_k}^d)^2 + (\sum_{k' \in K_U^d} \bar{w}_{tk'\tau_k}^d)^2}}{\bar{v}_{tk\tau_k}^d \sum_{k' \in K_U^d} \bar{v}_{tk'\tau_k}^d + \bar{w}_{tk\tau_k}^d \sum_{k' \in K_U^d} \bar{w}_{tk'\tau_k}^d},$$

**Step 5:** Find that item  $k$  whose effective gradient is the largest in a period, i.e.,

$$G_{kd} = \max\{G_{k'd} : (k',d) \in \bar{K}_C\}.$$

**Step 6:** Accept  $k$ . Let  $K_U \leftarrow K_U + \{k\}$ ,

$$A_U^d \leftarrow A_U^d + (\bar{v}_{tk\tau_k}^d, \bar{w}_{tk\tau_k}^d), z \leftarrow z + v_{tk\tau_k} r_{tkd},$$

$K_D \leftarrow K_D - \{k\}$ ,  $x_{tkd} \leftarrow 1$ . Then, goto **Step 2**.

**Step 7:** Let  $z \leftarrow \hat{z}$ ,  $x_{tkd} \leftarrow \hat{x}_{tkd}$ ,

$$y_{d1}^s \leftarrow V_d^s - \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} v_{tk\tau_k} x_{tkd}, \forall \notin \tilde{T}, s \in \tilde{S},$$

$$y_{d3}^s \leftarrow W_d^s - \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} w_{tk\tau_k} x_{tkd}, \forall \notin \tilde{T}, s \in \tilde{S},$$

$$z \leftarrow z + \sum_{s=1}^S p \sum_{d=1}^T (q_{d1}^s y_{d1}^s + q_{d3}^s y_{d3}^s),$$

$\hat{z} \leftarrow z, \hat{x}_{tkd} \leftarrow x_{tkd},$   
for  $t \in \tilde{T}, k \in \tilde{K}_t, d \in \{\tau + 1, \tau, k\}.$

**Step 8:** If  $K_D = \emptyset$ , the procedure terminates. Otherwise, let  $z \leftarrow 0, y_{di}^s \leftarrow 0$ , for  $s \in \tilde{S}, d \in \tilde{T}, j \in \tilde{J}, i=1,2,3,4$ , and proceed to the next step.

**Step 9:** we set

$$G_{kd} \leftarrow \frac{\sqrt{0.125} v_{tk\tau_k} r_{tkd}}{v_{tk\tau_k}^d + w_{tk\tau_k}^d}, \text{ for } k \in K_D.$$

**Step 10:** Let  $G_{kd} \leftarrow \max\{G_{k'd} : k' \in K_D, d' \in \{\tau + 1, \tau, k\}\}.$

**Step 11:** Let  $K_D \leftarrow K_D - \{k\}, x_{tkd} \leftarrow 1.$

**Step 12:** For  $d \in \tilde{T}, s \in \tilde{S}$ , if  $V_d^s \geq \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} v_{tk\tau_k} x_{tkd}$ ,

$$\text{then } y_{d1}^s \leftarrow V_d^s - \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} v_{tk\tau_k} x_{tkd},$$

$$\text{otherwise, } y_{d2}^s \leftarrow \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} v_{tk\tau_k} x_{tkd} - V_d^s;$$

$$\text{if } W_d^s \geq \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} w_{tk\tau_k} x_{tkd}, \text{ then}$$

$$y_{d3}^s \leftarrow W_d^s - \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} w_{tk\tau_k} x_{tkd},$$

$$\text{otherwise, } y_{d4}^s \leftarrow \sum_{t=1}^d \sum_{\substack{k \in \tilde{K}_t \\ \tau_k \geq d}} w_{tk\tau_k} x_{tkd} - W_d^s;$$

$$z \leftarrow \sum_{t=1}^T \sum_{k \in \tilde{K}_t} \sum_{d=t}^{\tau_k} v_{tk\tau_k} r_{tkd} x_{tkd} - \sum_{s=1}^S p \sum_{d=1}^T \sum_{i=1}^4 q_{di}^s y_{di}^s$$

**Step 13:** if  $\hat{z} < z$ , then  $\hat{z} \leftarrow z, \hat{x}_{tkd} \leftarrow x_{tkd}.$

Otherwise,  $x_{tkd} \leftarrow 0.$

**Step 14:** If  $K_D = \emptyset$ , the procedure terminates.

Otherwise, let  $z \leftarrow 0, y_{di}^s \leftarrow 0$ , for  $s \in \tilde{S}, d \in \tilde{T}, j \in \tilde{J}, i=1,2,3,4$ , and goto **Step 10**.

### 3. EMPIRICAL RESULTS

In this section, we implement the heuristic algorithm EBHA and compare its solution to optimal solution or LP (relaxation) optimal solution (as the upper bound for optimal solution). The algorithm has been coded in C++ and run under Microsoft Windows Server 2003 Standard Edition using a Server (Intel(R) Xeon(TM) CPU 3.06GHz and 1.0GB of RAM). CPU times were obtained through the C++ function clock(). To conduct our experiments we used randomly generated instances.

For each set of parameters T and K, we generated 10 random small scale instances, for which optimal solutions can be obtained by CPLEX 8.0. We tested heuristic solutions and optimal solutions or LP optimal solutions for all 10 instances, and tabulated the average relative gap and average computation time. Let  $z_P$  be the optimum of LP relaxation,  $z_H$  be the lower bound by heuristic and  $z_O$  be the optimum of the problem. In table 1, the relative gap  $g_O$  is defined as

$$(z_O - z_H) / z_O \times 100\%.$$

In table 1 and table 2, the relative gap  $g_L$  is defined as

$$(z_{LP} - z_H) / z_{LP} \times 100\%.$$

Table 1 shows the results obtained for a set of small test problems. Test problems 1 have 2 scenarios, 2 periods and 150 items (cargoes); test problem 2 has 3 scenarios, 3 periods, 4 destination ports and 71 items, and so on. For comparison, the optimal solution has been computed using CPLEX 8.0. As can be seen from table 1, the obtained results seem to be encouraging. The gap between the optimal solution and the heuristic solution is small and the computation time is very short. Table 2 shows the results obtained for a set of large scale problems.

From our preliminary computation experiment, we believe that heuristic algorithm would be a very good candidate for solving the problem in time critical or real-time applications such as capacity allocation in e-booking control problem where a near optimal solution is acceptable, and fast computation is more important than guaranteeing optimal value.

### 4. SUMMARY

Critical to the e-booking control problem is understanding sea freight marketing environment and optimization technique, its impact on the utilization of available capacity and service route planning for liner operator. Since customer behavior and characteristics are highly varying and not known in advance, we develop a stochastic pricing model which tracks customer behavior as well as the arrival process to maximize profit. On the other hand, we have formulated the capacity allocation problem as the two-stage stochastic mixed integer programming model, and presented effective heuristic algorithm which provide fast and near optimal solution. We also presented experimental results to evaluate the algorithm using a wide range of problem instances. The results strongly suggest that the heuristic algorithm is very effective for time critical tactical or operations level decisions, where a near optimal solution is acceptable and fast computation is more important than guaranteeing optimal value.

# E-Logistics Comparative Positioning Model: A Multi-National Enterprise Airline Study

John Hamilton

Director of E-Business, James Cook University, Cairns, Australia 4870

John.Hamilton@jcu.edu.au

## ABSTRACT

By capturing the hidden value in the multi-national enterprise's (MNE's) supply-chain in areas such as quality, value and innovation; logistics providers can increase the MNE's operating efficiency and enhance its capital utilization, within and enhanced competitive advantage framework. Today, many multinational enterprises (MNEs) use the global communication channels of the internet to strategically move their global activities to more competitive positions. The trend has been to outsource more and more of their non-strategic business functions, with their logistics providers acquiring these new sources of business. These logistics providers are classified as 1<sup>st</sup> to 4<sup>th</sup> party logistics providers [1]. A 4<sup>th</sup> party logistics provider (4PL) offers the complete supply side coordination solutions for the MNE, plus a degree of demand side coordination service [2].

At its peak, the MNE-logistics provider model activates the entire service value chain. Here the 5PL delivers a value chain level of both outsourcing and service. The complete integration of the value chain logistics provider with its vast array of 'added-value skills' and its block of partnered MNEs, yields a unique, innovative, flexible and highly agile partnership, whereby pathways towards 'sustainable' competitive advantage [3] may be developed, and possibly maintained. The MNE, whilst maintaining its final assembly, branding, research, and innovation functions, is increasingly becoming a service orientated, highly 'front-end' (or customer focused) operation.

This paper develops a technique to ascertain the positioning of MNE and logistics provider(s), and where the logistics provider – MNE integration level may be enhanced.

**Key Words:** logistics, airline industry, service industry, value, logistics provider, competitive advantage, strategy

## 1. INTRODUCTION

The role of logistics in business has developed over the past fifty years in both scope and strategic importance [4]. Logistics is the management of acquisition, storage, transportation, and delivery of goods throughout the supply chain (businessranks.com). Logistics strategies have influenced customer selection, product design, alliances and many other core business processes[5], and are closely aligned to the business supply side[6]. In the US the outsourcing of IT jobs has resulted in the creation of twice as many jobs as those displaced[7]. The Information Technology Association of America March 2004 report predicts that total savings of global logistics outsourcing policies will deliver total savings of US\$20.9B by 2008 (up from US\$6.7B in 2003, delivering new competitive realities within the business environment.

To be economically productive in the logistics arena the modern MNE should strategically utilize its service supply chain. Leading MNE's are steadily strengthening their 'front-end', downstream, customer-centric and 'innovative research' functions and supply chain structures[2]. They are aligning their key logistics provider(s) and supply chain(s) into a synergistic and globally competitive, strategic solution-set of operations [8]. Their intense, demand chain driven customer focus has yielded new methods of customization and 'one-on-one' 'customerization' [9]. These leading MNE's have

outsourced more and more of their non-strategic business coordination and functions to logistics providers [2],[10]. The logistics provider has been classified as either a 1<sup>st</sup> party logistics provider (1PL) ) such as the mail room; or a 2PL – like the warehousing function; or a 3PL, [8] – like the full transport and storage system; or a 4PL [1] – like the full transport and storage system for several organizations. The logistics classification grouping is based upon the degree of complexity, and the number of business functions under the logistics provider's control, with the 4PL offering the most complex, integrated, cost efficient supply chain solutions.

Recent logistics developments have incorporated the customer driven demand chain into the peak logistics solution. As the required new metrics are unfolding [11], a 5PL progression pyramid [12] is developing with leading MNE's. This progression pyramid is displayed in Figure 1. The 5PL model may also be aligned with the customer relationship model [13] as displayed in Figure 2. The 5PL solution typifies the MNE's strategic vision to target and enhance its valuable, loyal customer relationship.

The 5PL level of outsourcing and service has been conceptualized as a fully activated demand-supply logistics model - termed the 5PL FADS model [6]. Here the supply chain responds to the customer driven demand chain delivering a value chain solution that moves the MNE and its 5PL to a new internationally

competitive position delivering both low cost and high operational efficiency [3]. The MNE is then able to focus on its core business – its final ‘one-on-one’ ‘customerized’ assembly; its innovations, its research; its super-efficiencies, its internal business processes, and/or its individually targeted marketing solutions.

The 5PL model remains the next step in the progression to total logistics integration. The move to increasingly sophisticated, highly-coordinated logistics outsourcing solutions is often driven by the short term focus of senior management personnel, who have short term tenured positions, and who must deliver rapid results for the shareholders. Companies like Dell, eBay, Amazon, Yahoo are moving down this path with great success.

Warren Buffett[14], offers more cautious longer term solutions – and his business improvement and management strategies are equally successful. However, one of Buffett’s recent strategies was to gamble (an unusual strategy for Buffett) against the US dollar and to move large billions of US dollars offshore. This typifies the dynamic nature of executive strategic management today – many avenues are explored, and logistics outsourcing is but one of these avenues for efficiency growth.

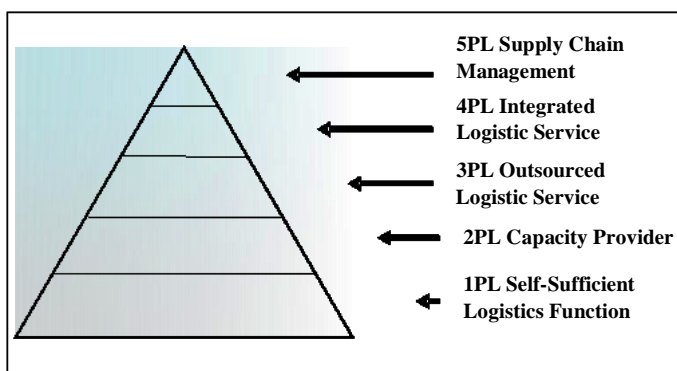

Figure 1: The Morgan Stanley 5PL Model, adapted from Morgan & Stanley[15]

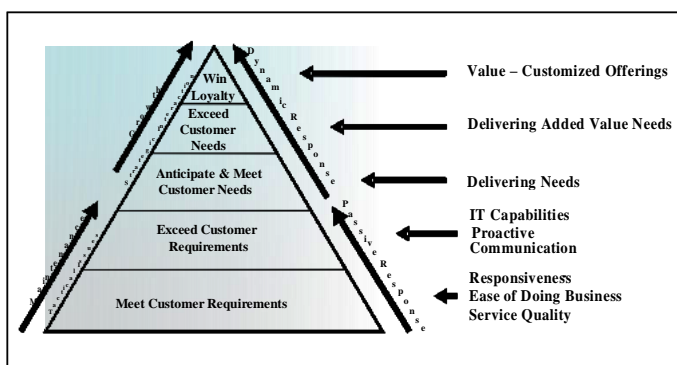

Figure 2: The Customer Relationship Hierarchy Model 5PL Model, adapted from Kuehne & Nagel [16]

The logistics outsourcing solution has been shown to deliver a wide raft of efficiencies, flexibility, cost savings and expertise. For example, thirty years ago

FedEx ([www.fedex.com](http://www.fedex.com)) was just another start-up company. Today it is a US\$25B reliable, responsive, relentless, and remarkable delivering the right mix of transportation, information, documentation and supply chain solutions in a wide variety of global customers in 215 countries (and often within 48 hours). FedEx (today a 4PL) has delivered great savings to its corporate partners. Hence for companies that encounter the customerized one-on-one information imperative logistics outsourcing is a means to create efficiencies.

The higher level PL systems deliver lean logistics solutions. Here the superior ability to design and deliver systems to control movement and geographical positioning of raw materials, work in progress and finished inventories at lowest cost[17] delivers a value stream[18]. These lean logistics systems work best for larger businesses with sufficient resources and bargaining powers to deliver such systems[19].

Successful logistics outsourcing can deliver great rewards. For example, in the US telecommunications industry the total logistics costs for companies regarded as ‘best-in-class’ logistics providers equate to 7.3% of revenue (the medium logistics cost for the industry is 14.3% of revenue). For a \$1B company this equates to saving \$70M annually[16].

Over the next five years, it is predicted that the rate of growth in logistics in the US will be between 15% and 20% per year. In 2003 the value of the US logistics industry was US\$910 B (logistics institute). This paper explores ways for a MNE to recognize its current positioning; and to use this knowledge to move to closer to the apex of the logistics outsourcing model - the 5PL solution. It demonstrates how the MNE may tease out its key levers, into a relevant set of measures. It allows the MNE, its key logistics providers, and other service supply chain partners to determine where their solution set is currently positioned. It then suggests the areas in which the MNE should provide additional focus, and thus move to a more competitive and sustainable position.

Recent developments in networked internet linkages, intelligent database interrogation software, alliance partnerships, and outsourcing have moved the leading edge MNE’s into the 4 PL arena (and towards the 5PL area). To measure their relative or comparative positioning tools like the Four Clusters Logistics Model [6] have been developed.

## 2. THE FOUR CLUSTERS LOGISTICS MODEL

The Four Cluster Logistics Model developed by Gunesh & Hamilton, incorporates four clusters of outsourcing levers. These are presented in Table 1. The model is displayed in Figure 3. Logistics providers partner with MNE’s and develop improved solutions to non-core outsourced MNE business units or functions. A simple

1PL solution may involve outsourcing of the staff canteen, the mail room, cleaning and the like.

Cluster 1: Technical Levers	Cluster 2: Soft-Skill Levers	Cluster 3: Institution al levers	Cluster 4: Characteriz- ation levers
<ul style="list-style-type: none"> <li>• Information Technologies</li> <li>• Communication Technologies</li> <li>• DSS Technologies</li> <li>• Organization Technologies</li> <li>• IT-Infrastructure Assets</li> <li>• Technical Ability</li> <li>• Logistics Knowledge / Know-how</li> <li>• SCM Knowledge</li> <li>• IT Knowledge</li> </ul>	<ul style="list-style-type: none"> <li>• Social Competency</li> <li>• Intercultural Competency</li> <li>• Interpersonal Competency</li> <li>• Communication Skills</li> <li>• Organizational Skills</li> <li>• Problem-Solving Skills</li> <li>• Leadership Skills</li> <li>• Team Orientation</li> <li>• Empathy</li> <li>• Integrity</li> <li>• Self-Assurance / Self-Awareness</li> <li>• Motivation / Creativity</li> <li>• Politeness / Diplomacy</li> <li>• Mobility / Flexibility</li> </ul>	<ul style="list-style-type: none"> <li>• Government Legislation</li> <li>• Industrial Policies</li> <li>• Company Laws</li> <li>• Financial Services regulation</li> <li>• Intellectual Property and Copyrighting Policies</li> <li>• Competition and Antitrust legislation</li> <li>• Corporate Governance and Transparency</li> <li>• Transport Policies</li> <li>• (Road, sea, air &amp; Rail)</li> <li>• Political Stability</li> <li>• Economic Growth</li> </ul>	<ul style="list-style-type: none"> <li>• Agile Customer Relationship Management</li> <li>• Reliable Communication Technologies</li> <li>• Integrated Organizational Technologies</li> <li>• Database, Web Interface and Knowledge Management Technologies</li> <li>• Responsive Database, Web Interface and Activated Business Intelligence</li> <li>• On-line 'Customerization' and Management</li> <li>• Responsive Flexible Demand Chain</li> </ul>

Table 1: Four Clusters Logistics Outsourcing Levers, from Gunesh & Hamilton[6].

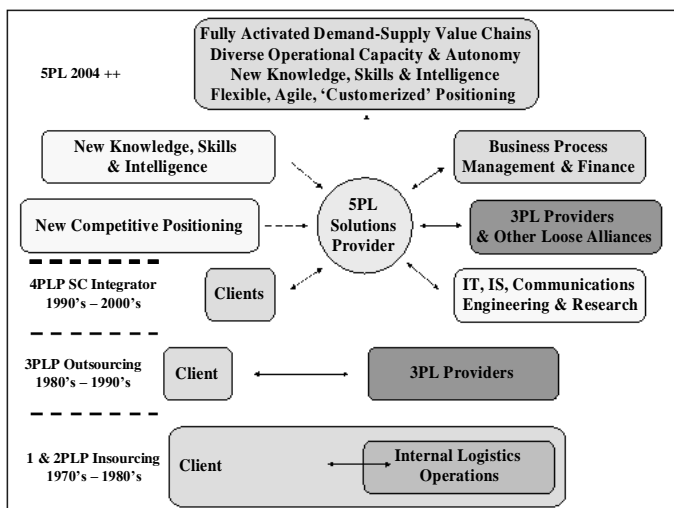

Figure 3: SPL solutions provider model, adapted from Gunesh & Hamilton[6]

In delivering the various levels of logistics outsourcing, the logistics provider engages an array of levers. The levers displayed in Table 3 constitute ways in which the logistics provider may generate a more competitive position. Measuring the MNE's ability to activate these levers gives a measure as to the degree of logistics capability the MNE possesses. It is generally cheaper for

the MNE to outsource its logistics functions. A 5PL utilizes all levers, combining and activating them to deliver responsive, value-adding, agile, personalized, competitive solutions to the 5PL-MNE partnership.

Gunesh & Hamilton's 5PL Logistics Model incorporates these four clusters of outsourcing skills into their current 'state-of-the-art' model. They propose that the 5PL opens the value chain pathways for possible 'sustainable' competitive advantage.

This model offers the conceptualization of how new value creation methods, lean supply networks, targeted value-adds, additional added value supplier networks, client side connectivity, customer responsiveness, demand driven value chains and the like may provide ways to increase overall profitability. Such a mix of skills provides a greatly reduced scope for direct competition, as it offers complete value chain solutions from the customer to the base level supplier. Some leading edge companies like Dell, IBM and Farmer's Info are approaching this level of value chain delivery.

### 3. RESEARCH FOCUS

The Director General of the International Air Transport Association (IATA), Giovanni Bisignani believes the industry must simplify the business [20]. He suggests the rules are outdated and often bilateral in nature, the cost flexibilities and labour structures are outdated, and the lowest cost solution is a non-viable one. He believes operational logistics must become highly automated and interconnected, and that with extensive use of efficient IT (and related technologies) future, flexible, agile solutions.

#### 3.1 Overview

This research uses the Four Clusters Outsourcing Levers. It develops and tests the website interface as a logistics outsourcing tool for the international airlines industry. Questions were addressed such as: 'Can the four cluster model levers be measured?' 'Do these levers provide a way to compare websites?' 'Does the four cluster model show the MNE where it may strategically arrange, or change website features to better enable its desired level of logistics?' 'What is the relative benchmarked position of the MNE?' and 'Should the MNE outsource its value chain logistics?'

To complement the content analysis, a survey and a set of interviews were conducted. The survey assessed consumer perceptions concerning travel industry websites and their service offerings. This survey data was collected from the travel industry and from the travel seeking (or participating) customer perspective. In addition a clutch of interviews helped to provide an understanding of the online travel business requirements from the perspective of their logistics outsourcing to other market players - be they low (1PL) or high level (5PL).

Drivers to activate the lever drivers in the four clusters model were identified, refined and added to the model. Multiple data capture methods included: websites and other electronic communications like email, FAQ's; company interviews (marketing and IT executives); and web based surveys of both potential and current customers were incorporated. These additional approaches added greater homogeneity [16] to the study. Mingers[21] and others also suggested that a multi-methodological approach, combining different research methods, yielded greater reliability, and richer research results. The developed drivers were coded, and used to measure the MNE's logistics potential.

### 3.2 Content Study

Content analysis was used to identify, code, refine and categorize primary patterns in the data[22]. A culling process was used, whereby constant comparative analysis refined the research delivering fuller descriptions and greater homogeneity. The coding of cluster levers was monitored and assessed. A focus group checked the coding of data at two levels – the manifest content level (physical presence of the data), and the latent content level (reading between the lines). Berger[23] suggested this approach is a communication media research technique based on quantitative means.

### 3.3 Data Coding

Based on prior studies[24], standard data-collection [25] and measurement criteria[26],[27] each MNE website lever feature was binary coded (present (1) or absent (0) against the predetermined model. A score of 1 meant the feature (driver) identified were present, whilst a score of 0 indicated absence. To help limit remaining subjectivity rules a range or a list of acceptable requirements were defined. The elements with performance within the accepted range or meeting the requirements were judged as '1', otherwise they were scored as '0'. For example, page load speed was coded based on industry standards. Thus one ('1') indicated within standard and zero ('0') outside the standard. The major advantage of this coding is that it maintained objectivity. Each site was assessed three times in order to minimise or eliminate judgment variance. Microsoft Excel was used for coding. This research was conducted during May, 2004.

Interpretation of the data offered a mechanism whereby competitive advantage adjustments and/or added-value solutions could be assessed and possibly incorporated into future MNE strategies. Using the above criteria, thirty different, IT-skilled, data-collectors rated each website. Their results were averaged. The relative position of the MNE against its competitors was determined. Major travel agencies (airline website logistics providers) were evaluated and also benchmarked.

### 3.4 The Four Cluster Outsourcing Levers

The four clusters, displayed in Table 1, each encapsulate

several levers, which, in turn consist of different features (drivers). 100 drivers were identified across the four cluster analysis, and 79 significant measurable drivers were utilized. A sample of the lever drivers identified for cluster 2 is displayed in Table 2.

## 4. STUDY METHODOLOGY

In this research a predefined logistics comparative positioning model was developed. It was adapted from earlier research[6], regarding virtual benchmarking of website design features and the four clusters outsourcing levers. This model incorporated techniques adopted by worldsbestnetwork.com, w3c.org; and others[6],[24],[26], [27]. These content analysis component techniques provided the basis from which the four cluster logistics driver model may be developed. A multiple lever, multiple feature model, capable of comparing, rating and benchmarking selected websites is developed. Data collection used 34 of the 340 global MNE airlines, and 5 of the 50 high-level global travel logistics companies. These thirty nine websites were systematically analysed to refine, and test this new logistics comparative positioning model.

Greaver's[28] twenty logistics outsourcing factors, and selected elements from Whiteley's 14 parameters model, were used to cross reference Gunesh & Hamilton's lever drivers model. All twenty logistics outsourcing factors, and Whiteley's parameters were suitably incorporated into this study. Hence a tailored comparative positioning model was developed. This model consisted of 79 drivers representing 42 levers.

Cluster 2	
Levers	Drivers
Social Competency	About us
Intercultural Competency	Multilingual, Copyright/trademark
Interpersonal Competency	Returns policy/cancellation
Communication Skills	Email/SMS, Phone, Fax, Contact us
Organizational Skills	ISO, Economic value
Problem-Solving Skills	Calculators/totals/order processing, Customerization
Leadership Skills	Management experience, CIO/Bios
Team Orientation	# Employees presented
Empathy	Treat customer as 1st person, Auto response
Integrity	Guarantee, Delivery time guarantee
Self-Assurance / Self-Awareness	ISO, International stds/awards
Motivation / Creativity	Customer service
Politeness / Diplomacy	Language, Multi-cultural language
Mobility / Flexibility	Tailormade product

Table 2: Lever Drivers for Cluster 2 – Soft Skills Levers, adapted from Gunesh & Hamilton, 2003[6]

Within the second soft skills cluster, 'social competency' is portrayed on the website by 'about us'. This incorporates 'treatment of company info'[27] and organization reasons[28]. Interpersonal competency is exemplified by the returns / negotiation / cancellation policy and communication skills. Mobility/flexibility is viewed via tailor-made product capabilities, incorporating functions like customer seat mapping, and superior provider performance[15]. Similar comparisons

were developed for each driver. Similarly, survey data was added in an effort to further enhance the model.

## 5. DISCUSSION

### 5.1 General

This exploratory research suggests many airlines pay little attention to utilizing their websites as a customer relationship tool. Indeed many rarely update their sites, some even refuse to allow email contact, suggesting phone calls offer better direct contact solutions. Many sites are poorly secured, poorly coded, and make little attempt to deliver a customer-centric approach. The core business should be to win customers, deliver the services they want, offer alternatives, and make websites user friendly. In numerous sites the customer must specify day and hour of flying, there is no option for 'anytime' to capture all options on that day. The realm of transactions is also poorly constructed. This area offers considerable opportunities to develop value-added packages, but little attention is focused in this direction. This research adopts a present ('1') or absent ('0') approach, so that a computer benchmarking program for logistics outsourcing may be developed. This program will incorporate the cluster model lever drivers approach.

### 5.2 Data Analysis

Data collected from 34 MNE airlines and 5 major logistics providers (travel agents) websites, was tabulated in excel. A summary of this data collection is displayed in Tables 3 and 4, and Figures 4 and 5. Table 3 uses a '1' to indicate the feature was represented, and a '0' to show the feature was not present.

Table 4 summarizes the four cluster analysis. Means, standard deviations and ratings were determined. Overall ratings were displayed graphically using spider charts (refer Figures 4 and 5).

The top 10 world airlines were included in this study, as were the top travel providers. Emirates, a growing privately operated airline, and other smaller MNE airlines were sampled. The best rating airline websites were deemed to be the Qantas and Singapore airlines websites, whilst a sample of weaker websites included: Yeti, Cebu Pacific, Australian and NZ airlines.

The relative benchmarking position for each MNE airline and for each airline travel logistics provider indicated that the MNE travel logistics providers indeed activated more lever drivers than did the MNE airlines. In every case the MNE logistics providers rated more highly than the MNE airlines analysed in this logistics analysis.

Some weaknesses within the MNE airline website industry lie in the areas of customer recognition and customer added value offerings. In many instances MNE airline websites do not allow for rapid change, depth of search, or rapid customer related response. This is, in part, due to the way tracking tools are utilized, and a lack

of intelligent knowledge management, and suitable interpretation structures used throughout these airline-related websites.

Table 3 indicates a range of approaches towards MNE websites. Some sites are rarely updates, lack high level security at least in parts of their sites, are not well programmed, do not allow ready communication, do not incorporate added-value solutions, and the like. It may be argued that these features do not fit the strategic objectives of the MNE. For example, a focus on airline ticketing may be the primary purpose of some sites. However, neglecting other website dimensions means another MNE may deliver a far better service. Thus a competitive strategic positioning by another airline may result.

The lever driver presence for each cluster is expressed as a percentage, totaled and compared via a relative rating scale and a mean rating scale. The best website logistics performing MNE's were found to be the large airline travel agents. These operations activated between 82% and 97% of the available logistics related website lever drivers, whilst the best airlines – Qantas, Cathay and Singapore activated 85% and 86% respectively. Most airlines rated well below these figures.

Table 4: Airline &amp; Travel Agents Web Summary Data

The airlines averaged activation of 63% of possible lever drivers. Consequently, the large logistically focused travel agents were delivering better logistics solutions than those of their MNE airlines. It may be asked ‘why do airlines bother with their websites when they could divert customer traffic to airline travel sites?’

Figure 4: 4 Clusters Logistics Comparison Spiderweb

Figure 4 offers a visual presentation of the relative website logistics performance of various airlines and travel agents to deliver well planned logistics solutions. This study shows that airlines do not plan their websites in a logistically strategic manner. For example, the low level lever drivers are not developed first. There is scant indication of a logistics strategy in most airline websites, and little focus on a transition of relative outsourcing.

Many websites appear to be delivered in an ad-hoc manner. Some airlines do not get the basics right, and others attempt to tackle higher levels of logistics in a poor manner.

Figure 5: Overall Cluster Rating for selected MNE airlines and airline travel logistics providers

Figure 5 summarizes the logistics presence of the four cluster lever drivers. In this study, only one MNE – Travelcity.com is on-track to progress to a 5PL solution, and two others Zuji.com and Trailfinders.com are operating as 4PL's. The airlines studied generally rate lower and in the 3PL range, with Qantas, Cathay and Singapore airlines operating in the 4PL area.

## 6. STRATEGIC INTERPRETATION

Considering the growing global role of e-business, airlines need to consider what they hope to achieve from their web sites. Do they use their site to sell airline seats? If so they should reinvestigate what their core business is, and where they are focusing. From this research, it is apparent that MNE airline travel agent providers offer better solutions via their websites than do the individual airlines. This may be seen as expected, and as a justification for outsourcing! The MNE airline travel agent providers must enhance the customer value proposition, and do so in a cost effective way, in order to compete. They do this by offering added-value products, flight discounts, price and travel comparisons, travel packages, incentives, fast efficient services, and the like. Consequently the airlines have, in the past, used them to save costs and to source more customers - particularly those domestically-based customers, and home country international tourists who intend to travel internationally. Today, the major airline alliances deliver new ways to code share and to strategically move passengers between alliance partners. They have seen their overall passenger numbers grow. However, in the background, the scale and scope of MNE airline travel agents has been increasing. A new problem is emerging – the super MNE

airline travel booking brokerage house (or portal). This super brokerage house strategy is a high risk strategy to the airline industry in the long term. Qantas and other MNE Asian airlines have developed a travel brokerage house (or portal) to help control this situation – ‘Zuji.com’ is their model. This provider offers cheaper fares than can be obtained via the airline’s own website, and also offers comparisons between participating airlines.

This solution could allow Qantas to move all its customer bookings to zuji.com. Qantas website customers would then be diverted to this one central booking site, and a further leveling of the travel booking competition would arise. This may then change the nature of Qantas’s strategic website focus.

The zuji.com website is almost anti-competitive, and appears to be an attempt to block others in the airline travel businesses from capturing this brokerage house domain. It will not stop others, and in time, at least one key logistics brokerage house will emerge.

The zuji.com solution is still small scale when compared to Sabre’s ‘Travelocity.com’ solution. In both cases the airlines are being moved into higher levels of competition, and ultimately the industry will become more low-price driven, with less options for differentiation.

Whilst Qantas, Cathay and Singapore airlines deliver a quality travel service, they do not deliver the same levels of service as those provided by Sabre via its Travelocity.com website.

All large successful travel agent logistics providers are working at above the 4PL level. Hence, for MNE airlines to compete with their own MNE travel agents they must operate at similar levels, or concentrate on improving their supply line efficiencies and outsource these service functions.

The question remains for these MNE airlines where do they choose to focus – on improving their internal logistics, on outsourcing or on improving their core business. This research shows that these large MNE airlines have all selected to move individually and have left gaps in the market. Large scale, globally-connected logistics suppliers have moved in, created a market, and are delivering better solutions than those offered by the individual airlines. Consequently, the airlines are missing an opportunity. To rectify this situation the airlines may choose to:

- 1) reduce the commissions available to travel agents, and control ticketing through their websites
- 2) form a major regional conglomerate and out-compete the logistics suppliers
- 3) concentrate purely on transporting passengers in a cost effective, efficient manner

4) outsource all ticketing and related functions to a large 4-5PL like travelcity.com, thereby relinquishing their sales packages and follow Porter’s[3] 2001 model of cost minimization and efficiency.

This research infers many airlines who are operating without a tight strategic focus, may be more likely to encounter website related passenger ticketing logistics problems. They may become price-driven transporters, and the large MNE 4PL and 5PL logistics-focused airline travel agents could influence their marketplace.

## 7. CONCLUSIONS

The airline industry operates at a number of virtual levels, and their websites epitomize customer strategy – and none deliver highly customized or ‘one-on-one’ customerized sales-service related solutions.

The airline industry is highly competitive, yet it has not delivered on its prime purpose – to move the maximum number of people it can through its operational spheres of influence. By July 2004 no airline in the world has delivered a quality web-based logistics service to its customers. Each airline maintains a web presence, but this site is often outdated, modified in part at best, and not designed to actually make the passage of winning customers easy. Many sites evaluated, were somewhat user ‘unfriendly’. They were slow to load, some required cookie dumps before one could access them, some do not provide easy customer response avenues, and some did not allow for online bookings. This state of affairs has created a new business opportunity – one where airline travel agent logistics providers can move in, and possibly capture, an additional share of the MNE airline customer sales market. Hence, instead of the MNE airlines controlling, and working with, their chosen logistics providers, the logistics providers may quietly grow in size and develop a small degree of control within the industry.

These airline travel agents have positioned themselves to deliver greater levels of logistics related offerings that those offered by the airlines, hence justification for their existence can be argued as they deliver value added services to the customer, and do so in a more customer-centric manner.

This research indicates that the four cluster model levers can be effectively measured. It shows that airline website drivers can be developed for these levers, and that these may be used to develop a comparative positioning between MNE airlines.

Finally the strategic question still remains - Should the MNE outsource its value chain logistics, and does the size of a business give it protection from being moved towards a lowest price provider?

## 8. FURTHER STUDIES

On-going research aims to development both a refined computerized logistics model, and a scalable competitive positioning matrix [29].

# E-supply Chain's Implementation in a Transit Economy

Chen Lihua and Yan Tao

Guanghua School of Management, Peking University, Beijing 100871, China  
{chenlh,yant}@gsm.pku.edu.cn

## ABSTRACT

In the worldwide, firms are increasingly paying their attentions to the integrated Web-based supply chains or e-supply chains because e-supply chains could enhance firms' efficiency and competitiveness. There have been some off-the-shelf products available for supplying activities. But how to establish an efficient e-supply system and how to successfully implement it in the supply process are not as easy as what expected. We propose an implemental and general supply chain framework with various techniques for different supply chain requirements in a transit economy. In a transit economy, the main challenge is to design an e-supply system such that it can be implemented efficiently according to the special supply chain environment of a transit economy.

**Keywords:** e-supply chains' implementation, efficiency and competitiveness, transit economy

## 1 Introduction

A supply chain refers to a chain which links each element of the manufacturing and supplying process from raw materials to the end customers, concerning with several organizational boundaries. Supply chain can also be further expanded to include recycling or re-use process. Recently, supply chain has been defined more practically as a connected network with organizations (e.g. suppliers, original equipment manufacturer, distributors, transporters, etc.), resources, and activities of creating and delivering various values in the form of both finished products and services [9] [16] [17] [7]. Nowadays, business firms are more interested in exploiting the integrated supply chains because they want to reduce cost, enhance efficiency and competitiveness, and accelerate the response to the market demand [12][18] [24] [20][26]. As business-to-business transactions based on the internet are increasing, it is becoming critical that firms rely on Web-based supply chains or e-supply chains to provide almost real-time response to market [16] [25] [13]. Thus, many famous IT companies such as i2 Technologies and Manugistics have provided a variety of supply chain software packages and some integrated

suites like mySAP and Oracle li. But for different firms, implementation solution can't keep same. How to figure out this problem? In this paper, we present a practical framework for e-supply chain in a transit economy, which not only can deal with the complexity of operations in e-supply chain system, but also be able to integrate the alliance of the supply chain. In the paper, we consider seven classes of firms with different level information asymmetry. For each level of firms, we proposed a uniform implementation solution based on their available information systems. We use the information asymmetry but not the complexity of operations to class the firms because information asymmetry is more critical than the complexity of operations in e-supply chain management. First, some operations are comparative simple, and need to be managed by IT tools due to the severe information asymmetry. Second, many complex operations are designed to avoid information asymmetry. Finally, eliminating information asymmetry can provide more evaluation to the performance of firms. In a transit economy, firms are developed in a different environment from usual. In many industries there exist some kinds of government intervention, which is

special serious in state-owned firms. So government regulation and role are important factors that shouldn't be ignored in establishing an implemental framework of e-supply chain system. We organize the paper as follows: in the section 2, we first describe the status quo of information system in transit economy which is based on the interviews with many directors of IT companies' marketing departments in a transit economy, and discuss the existed and latent challenges in a highly integrated supply chain from three perspectives: internal challenges, external challenges and government challenges. Section 3 dedicates to propose the implementation framework that identifies various solutions to the different e-supply chain related to the three key factors. Finally, we conclude the discussion and make some remarks about our research.

## 2 E-supply chain systems

### 2.1 Characteristic in a transit economy

In a transit economy, usually, many business firms have established considerable foundation in the infrastructure of information systems and in its application, and meanwhile, most business firms have realized that supply chain management can enhance their efficiency and competitiveness. First, hardware and related investment has been almost ready in large or even medium size business firms in a transit economy. Second, information isolated islands are being eliminated and integrated internal operation systems are coming into being. Finally, the concept of supply chain is more and more popular to business firms due to the spreading of media organization and accelerating of the government. However, there still left many deficiencies in a transit economy. First, there are still many firms that do not pay enough attention to IT. Second, few firms have accomplished the strategic enterprise systems. Third, although many industrial chain have coming into being, few firms extend their systems to outside and achieve integration on the entire supply chain. Finally, many firms do not fully realized the importance of e-business and haven't take actual steps to make good use of the internet-based system.

#### 2.1.1 Opportunities

To implement e-supply chain system, there are

some opportunities in a transit economy. First, because industries rapidly develop recently and many industry chains have appeared in a transit economy, it is time to develop e-supply chain systems to enhance the supply chains' as while as firms' efficiency and to provide better customer service. Second, available systems can be easily updated by new technology and off-the-shelf software. Finally, government is going to pay great attention to the industry/supply chain management and to promote the development of powerful supply chain by various supports.

#### 2.1.2 Difficulties

There exist difficulties along with the development. First, the concept of supply chain accepted by most firms is far different from e-supply chain. Second, most firms are not so strong to support the implementation of an integrated e-supply chain system. Finally, there is a lack of leading firms in industry chains that have enough power to integrate the e-supply chain.

### 2.2 Implementation challenges in a highly integrated supply chain

We illustrate the complexity involved in creating and implementing the integrated e-supply chain system with the two tasks of the system. Both of the tasks were geared towards achieving competitive advantage by reducing inventory, avoiding delays, and providing better customer service. The two tasks are: (1) cooperatively planning among the supply chain and (2) rapidly responding to customer query [18]. Many studies have highlighted numerous problems faced by a firm in adopting complex systems like ERP for internal operations [10]. Similarly, the literature on inter-organizational systems has discussed the problems associated with the implementation of EDI systems that are largely limited to one-to-one relationships [14] [15][19]. But we found that the challenges involved in implementing integrated e-supply chains are more serious than the problems faced by an organization trying to adopt internal systems (like ERP) or inter-organizational systems (like EDI). Integrated e-supply chain systems are the extended enterprise resource planning systems in which diverse organizations need to work together virtually. We classify challenges to the organizations in a highly integrated e-supply chain system into three categories: challenges from inter-

nal of the organizations, those from external of them and those from government.

### **2.2.1 Internal challenges**

Organizations invariably require considerable resources to implement the highly integrated supply chain systems. First of all, the software packages for creating e-supply chain systems are quite expensive and need several powerful computers, database systems, and communications links to support. Secondly, it is particularly expensive to secure the installed highly integrated e-supply chain systems because in such systems: (a) public Internet is used to transport data, (b) many more partners than in traditional EDI systems are usually involved, and (c) data exchanged tends to be highly sensitive. Thus, an organization that implements a highly integrated supply chain system has to expend financial resources that will greatly exceed the expenses on many other information systems. Thirdly, organizations that implement integrated e-supply chain systems need to have highly sophisticated technology infrastructure in place. The IS literature has discussed how organizations get overwhelmed by the technology infrastructure needed for implementing a complex system like ERP [10]. Indeed, the infrastructure that can support a sophisticated and highly integrated e-supply chain system is more technical than others. Finally, the implementation of an integrated e-supply chain system need more reengineering of business process than any other information system does because not only internal business processes need to be integrated, but also these redesigned processes should work synchronously with those of external partners as well. Thus, while the e-supply chain system redesigns the business flows, it must keep accord with its business partners. As given that integrated e-supply chain systems will cause more changes than ERP or EDI, more organizational resistance arises during the implementation of such systems. Senior managers have to involve in the implementing process and devote a lot of time for such system to succeed. Therefore, before a firm creates an integrated e-supply chain, its senior managers have to carefully assess if they have the sufficient commitment, time, resources and abilities to manage the whole process of the firm's reform.

### **2.2.2 External challenges**

Challenges, called external challenges, which are related to bringing supply chain partners on-board and making them a part of the extended enterprise systems are as important as the internal challenges. Some literatures on inter-organizational systems have discussed the importance of business partners in the successful adoption of such systems. For instance, Hart and Grover in [15] and [14] respectively discussed the level of mutual trust which is needed for business partners to be willing to adopt electronic data interchange. In the implementation of an integrated e-supply chain implementation, mutual trust usually gets amplified because of the better relationship among business partners and because of the system's integrating strategies which is a major challenge and can improve firms' competitiveness in the system. While some business partners agreed to become a part of the system for their own benefit, others were reluctant in adopting e-supply chain systems due to resource, technical, relationship (trust and vulnerability) issues, or simply due to a resistance to change to a new way of doing business. On the one hand, the leading firm must have enough power or resources to make the partners adopt e-supply chain systems [15] [14]. On the other hand, in order to implement an integrated e-supply chain system the partners in the system also need large resources and a strong information technology infrastructure, somewhat comparable to that of the leading firm. Further, if the required functionality is built based on the partner's existing information systems, considerable amount of IT expertise for creating the interfaces of diverse systems will be needed. Finding such expertise in some partner organizations proves to be quite difficult, particularly if they are small [15] [14]. Thus, because of the massive financial, managerial, and organizational resources, a firm may give up the aim for a highly integrated e-supply chain. In this way, although the firm can minimize the challenges and reduce the risk of failure encountered during the implementation as while the firm also throws away the opportunities of cooperative development with the integrated supply chain. In order to figure out the paradox, we design some system-based implementation patterns for the different kinds of integrated e-supply chain systems such that the

system can be implemented efficiently with less challenges and risks.

### 2.2.3 Government Challenges

Above, we have analyzed major internal and external challenges involved in creating a highly integrated e-supply chain system. Now we turn our attention to the government challenges. Notice that many organizations in a transit economy usually have not had the resources, technical infrastructure, commitment, power over their partners, or resourceful chain partners enough to support the implementation of such complex systems, i.e., China is in a lack of powerful leading firms in industry chains. If only relying on the development of firms themselves, e-supply chain systems are too difficult to be implemented, which may delay to improve the firms' competitive advantage and lose the marketing chance. It is crucial for government to focus on some important industries and support them to integrate the whole value chain by e-supply chain system. These industries may include high technologies such as electronics, biotech and spaceflight, strategic industries such as automobile, steel and oil, former state monopolized industries such as banking, mobile and electric power etc. Government should play a different role to support firms at different developing stages to integrate an e-supply chain system. For example, for a newly arisen industry integrating e-supply chain system is unpractical and has no effect. The government should popularize the e-supply chain thought to firms along with favorable policies. When the industry grows up to an extent, there will be increasing need for sharing information and integrating supply chain, but usually few firms have enough power to lead this implementation. The government then can play a key role in promoting the establishment of a suitable e-supply chain system by providing an information platform and issuing some stimulant policies. Finally, how to set up and maintain the trust relationship between government and firms to avoid and punish cheat is a great challenge to a government.

## 3 An implementation framework of e-supply chain

Traditionally, the issue of e-supply chain implementation was studied based on following two

dimensions: complexity of a firm's internal operations and the firm's ability to integrate their external business partners into the e-supply chain. For complexity of operations, the determination of the suitable level of system's integration is critical [1] [21]. Usually, the complexity of operations is actually caused by information asymmetry. To eliminate information asymmetry rather than only to automate the operations, an e-supply chain system should be launched. Although many complex operations can be designed to avoid some kind of information asymmetry, some other kind of information asymmetry can only be reduced by e-supply chain integration. So, e-supply chain integration becomes a most promising area for the improvement of efficiency to the firm's whole value chain. A firm's ability to integrate its external partners into the supply chain refers to its ability to persuade the partners to participate in the chain, to create necessary infrastructure, and to redesign business processes to match the firm's supply chain system. Two main factors that will facilitate integrating external partners of a firm's supply chain are: trust between the parties and the power over the partners. The ability to persuade business partners to integrate their information systems with leading firm's is considered more important [15] [14]. On the other hand, for a developing country, business firms are not mature generally and they have not enough consciousness and power to integrate e-supply chain. To speed up the integration of e-supply chain in some important industries the government plays a pivotal role. In this paper, we propose the three-dimension implementation framework based on the consideration on information asymmetry, the firm's ability to integrate their external business partners into their e-supply chain and the government's regulation. As discussed above, the first dimension, the information asymmetry can apply to the firm's internal operations, external operations, or both (i.e., it has three levels). For the second dimension, the firm's ability to integrate partners into the supply chain, can be either high or low (i.e., it exists at two levels). For the third dimension, the government regulation in one industry may be strong or weak. Hence, we have  $3 \times 2 \times 2$  situations to classify the approaches to implement an e-supply chain. Note that in the situation

where a firm's information are only internally asymmetric, it is not necessary for the firm to integrate external partners and the government regulation will not play any important roles in integrating the supply chain. We, therefore, fold the four cells of our classification corresponding to the internal information asymmetry into one. Additionally, when the firm's ability to integrating is high, there is no need for the government regulation. Thus we fold the two cells of our classification corresponding to the external information asymmetry and high ability to integrate into one. And the same is applied to the two cells corresponding to the internal and external information asymmetry and high ability to integrate. These reduce the number of distinct e-supply chain implementation approaches to seven.

Besides the above issues, managers need to decide whether to build the required e-supply chain functionality based on their existing systems or to buy an off-the-shelf software package to automate and integrate their e-supply chain. Although integrating existing information systems into the new supply chain system can increase the technical complexity of the task, it really can reduce some of the challenges and huge investment which the new system causes, for example, which may need less investment, reduce changes in business processes and changes in procedures, and do not need more trained employees in the use of the updated system, etc. In fact, it is enough for the firms which have already installed certain software to buy additional components of the best-of-the-breed supply chain-related software from vendors, and then customize and integrate them into their existing infrastructure. Therefore, while deciding the approach to create an e-supply chain suitably, it is also very important for a firm to decide whether to build a supply chain system over its existing IT infrastructure or to buy an off-the-shelf software package. We take into account this buy-versus-build option while discussing each of the seven approaches included in our framework. This buy-versus-build decision has been considered to be a major issue in the system development [5][4] [22][23].

### 3.1 Strategic enterprise systems

A firm that falls in this cell mainly has internal information asymmetry and need more external integration than internal integration. This situation may happen, for example, when a firm has complex manufacturing operations, but most of its components and sub-assemblies are made in-house. Complex manufacturing operations are devised by multiple manufacturing facilities, assembly lines and numerous inventory storages for raw material, work-in-process, and finished goods inventory. How to share information among all these processes? The firm needs an internal integration so as to ensure the smoothly flowing of its information. Since external partners do not play a critical role in the manufacture of the product or its distribution, the firm does not need to concern with integrating business partners with an e-supply chain system. Sometimes, this approach may also be chosen when the firm does not have enough resources to manage both high internal and external integration simultaneously and it believes that it can more easily or effectively handle internal integration. Government here should stand by and give some general guidance. Under this scenario, if the firm's investment in its legacy systems is small or if such systems have outlived their usefulness, the firm may want to buy and adapt a standard software package. A suitable strategy for such a firm is to install strategic enterprise systems such as ERP systems. Since in this situation external linkages are less important, an appropriate e-supply chain strategy for the firm would be to share the output of its ERP system with external partners over a Web-based EDI linkage [2]. Complicated off-the-shelf packages for supply chain planning, execution, and logistics for integration with external partners will not be effective for such a firm. In the above approach of the e-supply chain implementation, the challenges that the firm encounters will be mostly internal, for example, how large amount of resources, how strong IT infrastructure, and how significant change in management effort. The requirement for the system security is limited in such cases because few internal data and networks need to be secured.

### 3.2 Operational external systems

A firm in this cell has mostly external information asymmetric and it mainly needs external integration while its need for internal integration is limited. This case may happen, for example, when a large number of components and subassemblies for the firm's production are provided by external partners, the firm mainly focuses on in-house assembly. In such a situation, it is important for the firm to create sophisticated linkages with external partners in order to optimize its external value chain. However, if the firm does not have a high ability to integrate business partners into a sophisticated e-supply chain system, it should aim for a limited integration with its partners. Thus, the appropriate strategy for such a firm is likely to create an operational external linkages in the areas like procurement and logistics. Thereafter, the firm can gradually expand the supply chain functionality to more strategic functions like collaborative planning, forecasting, replenishment, and integrated CRM. However, some firms may already have certain valuable legacy procurement and logistics applications that they may be using for achieving integration with partners through traditional EDI. In this case, instead of investing in new off-the-shelf applications and redesigning business processes for procurement and logistics to suit such software, the firm may simply establish a Web interface with these existing applications. During the implementation of this strategy, challenges will be mainly related to external partners because changes in internal operations are minimal. The firm will be required to devote resources to redesign operational external processes with its partners. To secure the supply chain data and network is important because the data are mainly exchanged in the external systems among partners when the firm has highly integrated external linkages.

### 3.3 Strategic external systems supported by government

Firms in this cell need the same external integration of an e-supply chain as firms in the cell of Operational external systems cell. Usually, the firms in this cell are comparable small in size but large in number. For each firm, it is inefficient to create operational external linkages separately.

But for the entire value chain, a industrial alliance linked by an e-supply chain may lead to great efficiency. Government can play the key role in supporting and organizing the alliance. Another case is that in some industries such as real estate, there will be great revenue due to information asymmetry and firms in these industries are reluctant to implement e-supply chain systems which means the decreasing of revenue. But for planning the whole country's resources, it is urgent to eliminate the kind of information asymmetry. Only the government have the motive and power to push the implementation of this kind of e-supply chain systems. The main options for the government are to establish information exchange platform, to constitute credit systems and to set up information publicizing platform, etc. Information exchange platform is to provide an exchanging channel for operational information. Based on this platform, firms in the value chain can share manufacturing, inventory, logistics and other operational information. Credit system is to constitute trust relationships among firms in a value chain. By this way strategic external systems can be set up in a much shorter period and integrate areas like collaborative planning, forecasting, replenishment, collaborative product design, and integrated CRM, which is called government support strategic external system. Information publicizing platform is mainly focus on the reducing inefficiency in the economy. Therefore, there are mainly two conditions that need the government to intervene. One is to support the setting up of e-supply chain systems to improve the efficiency of the whole value chain in which no firms has enough power to do this in spite of large number of firms in the chain. The other option is to force the implementation of e-supply chain systems to eliminate information asymmetry in some industries with unfair high profit. These two situations may mostly occur in the newly arisen and developing industries and also, there will be a lot of problems and chances in such industries. So the government should pay them enough attention and make them develop in the right direction. E-supply chain integration is a effective way to go through.

### 3.4 Strategic external systems

Similar to the previous cell, a firm in this cell mainly has external information asymmetry and need external integration with limited internal integration. However, this firm differs from the firms in the previous cell because it is able to more effectively integrate its external partners into the supply chain. The firm falling in this cell should seek supply chain integration with external partners in strategic areas like collaborative planning, forecasting, replenishment, collaborative product design, and integrated CRM. The firm falling in this cell will benefit from strategic external systems like the ones available from suppliers like Dichain, i2, Manugistics, etc. This option is particularly appropriate if the firm has made only marginal investment in legacy supply chain planning software or if its legacy supply chain planning software has run out of its useful life. These supply chain systems can, in turn, be linked with some standard database management software that may be sufficient to handle the firm's simple internal operations like inventory management and accounting. The firm needs to be conservative in its approach toward integration of the internal system, as high internal integration is not really needed in its operations. As such software packages like mySAP and Oracle11i that emphasize high internal and external integration may not be suitable for such firms. However, if the firm already has some valuable installed IT infrastructure, it may follow a different approach to creating its supply chain solution. For example, in the case that the firm may already have a system that it uses for demand planning, in order to create the e-supply chain system, the firm needs to create linkages between the existing demand planner and other internal systems as well as port the demand data over a Web interface for external connectivity, which will be substantial to build the effort on the part of the firm. Local IT solution provider such as Ufsoft, Kingdee, Dichain and Bokesoft are suitable for such firms. Main challenges in implementing systems of this cell's firms will be to get the necessary resources for supply chain integration with external partners in strategic areas like collaborative planning, forecasting, replenishment, and integrated CRM. The firm and its partners will also require technical sophistication to implement and

secure such systems. Additionally, the organization will face the challenge of redesigning business processes jointed with external partners in order to make the implemented systems efficient.

### 3.5 Strategic enterprise and operational external systems

A firm in this cell has information asymmetry both internally and externally, and, therefore, has a strong need for internal as well as external integration. However, since this firm does not have a high ability to integrate its external partners into the supply chain, it needs to carefully think through its e-supply chain implementation strategy. While it may appear attractive to the firm to create sophisticated e-supply chain systems that integrate well with business partners' systems, in the absence of adequate partner integration, the firm's efforts may not bear much result and may be an unnecessary drain on its resources. An appropriate strategy for such a firm is likely to be to focus on integrating their internal systems and create external linkages in areas like procurement and logistics. It can defer expansion of the supply chain functionality to strategic functions like collaborative planning, forecasting, and replenishment, and integrated CRM. If the firm does not have a strong existing IT infrastructure of value, the firm should consider the option of scrapping the existing systems and building this e-supply chain system from scratch. The firm in that case can create the requisite supply chain functionality by opting for some off-the shelf strategic enterprise software that enables integration of internal processes, and by creating operational linkages for procurement and logistics. On the other hand, if the existing information systems of the firm are adequately serving its needs for internal integration and the firm also has some applications in place for procurement and logistics, the systems building option for the firm could be to integrate procurement and logistics operations with the application for internal operations and establish linkages over a web interface with external partners. Major challenges in implementing systems corresponding with this cell will be related to implementing a strategic enterprise system and integrating its existing legacy systems with it. Thus, it will need considerable amount of resources, technical expertise, and internal pro-

cess redesign. The firm will also be required to devote resources to redesigning operational external processes jointly with its partners and to securing data and the network. However, considering the fact that the data exchanged is not likely to be so strategic in nature, a high degree of trust with the business partners is not very critical for implementing the external linkage.

### **3.6 Government support strategic extended enterprise systems**

The government's role is similar to that described in Government support strategic external systems.

### **3.7 Strategic extended enterprise systems**

Similar to the analysis in the previous systems, the firm in this case has information asymmetry both internally and externally. Therefore, it needs an e-supply chain solution to incorporate both internal and external integration. Moreover, the firm in this cell has high ability to integrate business partners into a sophisticated e-supply chain system. The firm can take two ways to integrate its internal operations and supply chain system: either through an off-the-shelf integrated software package or through a customized solution that integrates best-of-the-breed software packages and ports its output over a Web interface, as done by the electronics manufacturer. Two major initiatives in the off-the-shelf integrated category come from SAP (called mySAP) and Oracle (called Oracle11i). Both mySAP and Oracle 11i are relatively new systems that have not been widely installed. In fact, problems of compatibility with some existing applications that Oracle11i is reported to have, seem to have made some companies hesitant in implementing this software. Thus, the firm's IT experts may have to get deeply involved in the implementation process of these complex software packages and be ready to trouble-shoot some unforeseen problems. On the positive side, both SAP and Oracle have been in the market with their enterprise integration software for a long time and have the necessary expertise to facilitate the successful implementation of their systems. The second scenario might be that the firm has invested already in

some type of systems, e.g., internal connectivity software like ERP or supply chain software from vendors like i2 and Manugistics. Thus, it may not wish to scrap its investment in existing software solutions and start afresh with a solution like mySAP or Oracle 11i. In fact, it might retain of the best-of-the breed functionality offered by software from vendors like SAP, i2, Ufsoft, Kingdee, Dichain, Bokesoft, Manugistics and Siebel instead of committing itself to a single vendor software like mySAP or Oracle 11i. In such a situation, the firm faces with the task of integrating various systems at its end with those of its supply chain partners through a Web interface. This is indeed a complicated exercise and there are likely to be several implementation difficulties. Major challenges in implementing these supply chain systems will be those of integrating multiple systems within the firm as well as integrating them with business partners' systems. Considerable amount of financial resources and technical expertise will be required to make such integration possible and to secure the data and the network. Besides, the firm and its business partners will also be required to undertake substantial process redesign necessary for supply chain integration in strategic areas like collaborative planning, forecasting, replenishment, and integrated CRM.

## **4 Remarks and Conclusion**

Usually, the e-supply chain system is a comparable new concept to the firms in a transit economy. Though the idea is promising and many off-the-shelf products may have appeared in the market of a transit economy, how to implement E-supply chain system is still a great challenge to the firms. It is sure that there is not a uniform solution which can fit the different requirements and the various legacy system bases. This paper mainly analyzed the different roles of firms and government in the implementation of E-supply chain system and proposed an framework to implement e-supply chain systems in a transit economy.

# Experimental Study on Effect of Information Behavior by Media Representation Patterns of E-Commerce System

Jiangyu Li

School of Economic & Business Administration, Beijing Normal University, Beijing 100875, China

## ABSTRACT

The article made study on effect of different media representation pattern of the hierarchy in shopping-on-line system. The result shows that the effect of virtual reality representation pattern is better than that of Text in higher levels of the hierarchy, but more levels in virtual reality pattern increases the errors of user's activity. It also shows that the media representation pattern of first level have greatest impact on improving performance efficiency.

**Keywords:** shopping-on-line, virtual reality, hierarchy, media representation pattern

## 1. INTRODUCTION

In recent years, the development of Internet was growing enormously. While changing working pattern of humans, it also brings in another business model, say online shopping, its unique charming made itself a huge commercial future and even will change current existing traditional way of business model<sup>[6]</sup>. The study<sup>[2]</sup> found that visual reality pattern of commodity information involved in online shopping system can make buyers to give positive comments to commodity information and effectively arouse the buying desire of consumers. Therefore, that, factors in visual reality of commercial websites affect information behavior and shopping behavior of humans, gains a lot of attention from academic professionals. Those attentions can be interpreted as the following: the proceeding structure of consumers' visual experiences, and the relation between direct experiences of consumers and indirect experiences of consumers in visual reality system<sup>[9]</sup>; the applicability of design rules of shops in visual reality system compared to that of real life shops, and the study on the advantages of shops' individuation in visual reality system to consumers<sup>[10]</sup>. On the respect of media representative pattern, a primary finding is that representative pattern of shopping system in visual reality is in the better position for consumers to feel familiar in shopping process and have high frequency rate to complete buying tasks compared to that in Text pattern, while on the aspect of representative in systematical structure<sup>[11]</sup>, how does representative in visual reality affect consumers' information behavior still remains unclear.

As for the study on hypertext model, it was found that the overview was very important for the development of task strategy and working efficiency of the users because it constructed the mental map of users for the system<sup>[3,8]</sup>. Representative pattern will greatly affect the development of the overview, even affect the interactive way with the system. One effective method was to fully use established experience and inherent cognitive ability of users, using their familiar objects and activity model to metaphorically demonstrate interface information and

interactive model, which is called metaphor Model<sup>[1]</sup>. This understanding and practices had become the major pattern of representative and interaction of current information system. Visualization theory concerned perceived that users' inherent capability of understanding space and space's relationship should be utilized efficiently to allocate information. Therefore, different visualization utilization models are formulated [5,7].

The hypothesis is that hierarchies of shopping system in VR pattern will be easier for users to set up an overview of the system and formulate an effective interactive model, and it will be easier for users to formulate information cognition, but its efficiency of information activities (moves or actions in information space) maybe low due to its high frequency of going around to search objects compared to that in Text pattern, in this sense I suppose to draw a conclusion that VR pattern is better than that in Text pattern in higher level of hierarchy structure; VR pattern with more levels is easier for users to complete the task, but performance efficiency in Text pattern is higher than that in VR pattern, the understanding on the previous conclusion in online shopping environment needs to further test and examine.

## 2 METHODS

### 2.1 Subjects

30 subjects are from Beijing Forest University, they are all inexperienced computer and web users with average age of 20.5 years old, 22 of them are male subjects.

### 2.2 Experimental Devices

PC (Pentium 166), 14' Monitor, two-key Mouse.

### 2.3 Experimental Materials

To set up three on-line shopping centers The shopping centers use same 4+4+3+1 structures with four levels referring to shopping streets, shops, shopping berth and

commodities respectively and each level consists of four, four, three and one object respectively, say shopping streets have four shops with four shopping berths and each berth consists three items of commodities, and commodities has a list to describe its characteristics and indicate its name. The structure and objects of three shops are all the same. The first level at first shopping center will be presented with visual reality, and other levels will be presented with Text representative (hereinafter referred to as VR100) ; the first and second level at second shopping center is presented with visual reality, and other levels are presented with Text representative (hereinafter referred to as VR11) ; second level at third shopping center is presented with visual reality, and other level is presented with Text representative (hereinafter referred to as VR010) . Entering the first three levels of the shopping center hierarchy will be proceeded by moving rolling bar at the bottom of the screen (for text pattern) or walking (for VR pattern), and then view all objects or the whole shopping site. Shoppers can enter next level of shopping site by clicking object-text, also they can back up the previous level by clicking Exit or Back button. The last levels of three patterns are all the same with text representative. All materials and the facilitation of the experiment are based on the web, VRML, HTML technology.

## 2.4 Experimental Task

One target object will appear randomly from 48 objects, subjects should go round and view objects in shopping centers by moving mouse. Subjects choose “determine to buy” when they find target object in the fourth hierarchy, which indicates the completion of one object-searching task. Subjects will execute 20 searching tasks as fast and accurate as possible. Reaction time, objects selected and accuracy in different levels made by subjects will be recorded by computer in the whole process.

## 2.5 Experimental Design

One factor between-subject design was adopted.

**Independent variable** is referred to different representative patterns of shops, or each level of shops in visual reality, that is to say, which level is presented by visual reality. Independent variable has three levels with three representatives mentioned in experimental materials, each level is matching three treatments respectively. Thirty subjects are grouped into three teams (each team consists of 10 persons) randomly and allocated into three treatments.

**Dependent variables** are the following

1.Reaction time (RT) : Time subjects spent to complete one object-searching task, totally 20 object-searching tasks in the experiment.

2.Times of mouse movement (TMS) : Actual number of clicking when subjects process the task.

3.Mouse movement error (MME) : It means that the difference between actual times of mouse movement and necessary times of mouse movement for one task. The shopping center was divided into four hierarchies, and subjects must take at least four times of choices to find the object, in this sense, the actual times of one task would be four. Mouse movement error would be the difference between times of mouse movement and four. Controlled variables: Time delay during changes of different hierarchy level of the shopping center, and it takes 9 seconds to appear next level in each representative.

## 2.6 Experimental Procedures

30 subjects are grouped randomly into three teams with 10 numbers for each team and each team will conduct three treatments respectively (shopping center with three representative patterns). Under each treatment of Text, TCG or VR shopping system, subjects will read wording instruction first, and will perform for an exercise after understanding the instruction perceived by themselves in order to understand the whole tasks and requirement. The content of practices is irrelevant with that of the experimental tasks. Subjects should fulfill ten object-searching tasks during the practices and enter the actual performance of the experiment: as soon as target objects appeared, subjects will begin performing by clicking “Start”, then the first level of shop system, say shopping street, will be showing. The subjects will perform tasks until he or she find the target object and determine to purchase by clicking “determine to buy”, then the primary task is fulfilled, the next target objects appeared, and the second task begun. This process of objects-searching task will be performed twenty times by each subject. The computer will monitor the whole process and record all activities of the subjects.

## 3 RESULTS

The results are shown in table 1, effective subjects in three treatments are 11 persons, 8 persons and 8 persons respectively.

Review all data first (explore, SPSS 8.0 for Windows) and test the normality of the data, then conduct ANOVA analysis (GLM General Factorial in SPSS for Windows 8.0) . Reaction time doesn't include time delay of 9 seconds, unless it marked clearly.

### 3.1 Reaction time under different three media representative patterns (RT)

Figure 1. RT under different representative patterns

Table 1 : Reaction time under different representative patterns

	Subject	Mean (ms)	Deviation	Deviation
VR100	11	35685	12367	3530
VR110	8	44896	11141	10565
VR010	8	48905	18944	6313
Total	27	42331	14929	3741

Table1 showed that subjects completed task fastest in VR100, second fastest in VR110 and slowest in VR010.

Figure2 : RT of task stages under different representative patterns

ANOVA revealed that there was no significantly difference on task performance among three media representative patterns [ $F(2,24)=2.161$ ,  $p=0.137$ ], Post Hoc (LSD) Test found no significant differences among them as well(see figure1).

### 3.2 Reaction time of each task stage in media representative pattern.

In order to further understand the effect of three media representative patterns on information activity, a deeper research has been made to study the activity of subjects in different stage of tasks in three representative patterns. In this situation, we considered different task stages as additional factor, and divided it into three stages (or levels), first stage with first 7 tasks, second stage with 7

tasks in the middle, and third stage with last 6 tasks.

In considering of the requirement of data normality, we conducted changes ( $RT \rightarrow \log(RT+1)$ ). Figure 5 showed that the speed of development under each representative pattern was getting faster as task stages (levels) are developing, which indicated the strong effect caused by practicing. VR110 was the slowest in first stage, and the other two are very close in merit; VR100 was fastest both in second and third stage, VR110 in the middle and VR010 the slowest.

ANOVA indicated that there are significantly differences among three treatments ( $F(8,72)=5.785$ ,  $p<0.01$ ), and the main effect of representative pattern ( $F(2,78)=4.199$ ,  $p<0.05$ ) and the main effect of task stages ( $F(2,78)=0.629$ ,  $p<0.01$ ) are all significantly different. But there are no significantly differences in interactive function between the two ( $F(4,76)=0.897$ ,  $p=0.470$ ). Post Hoc(LSD) Test found that there are significantly difference between the two of VR110, VR010 and VR100; and significantly difference between the last two stages and the first stage (see figure 2).

### 3.3 Times of mouse movement (TMS) 、 Mouse movement error (MME) under different representative patterns

TMS and MME in VR110 are the highest. ANOVA

Figure 3. MME under different representative patterns

showed that there was no significantly difference on TMS ( $F(2,27)=2.828$ ,  $p=0.077$ ), and there was significantly difference on MME among the three ( $F(2,27)=3.914$ ,  $p<0.05$ ). Post Hoc(LSD)Test found significant differences between TMS and MME in VR100 VR 110 (see figure 3).

## 4 ANALYSIS AND DISCUSSION

This study showed that using VR in higher level under different media representative patterns results in better performance and higher behavior efficiency of consumers. At the first level, it reaches best performance in VR and worst in Text pattern. This leads a conclusion

that the position of VR appeared is very important under hierarchy structure of three representative patterns. The appearing of VR at first level and second level shows the opposite effect. Using VR at higher levels of hierarchy structure is helpful to lead performance efficiency, but using more VRs at more levels can't lead better performance, but increasing MMS that decreases the speed of the whole task. According to analysis mentioned before, VR at the first level help subjects set up an overview of the system, or setting up a relation between the existing experiences of the subjects and information target and behavior model of the subjects, that is better than that under Text pattern.

Conclusion can be made that VR has a better position to help subjects set up a systematic overview of media representative pattern; the first level in hierarchy structure is more powerful than others to set up a systematic overview of hierarchy levels.

### ABSTRACT

Supply chain management refers to all the management functions related to the flow of materials from the company's direct suppliers to its direct customers. In this paper, we will propose a generic supply chain management system, and describe how the system works in terms of information exchange, workflow coordination and flexible logistic route. We will introduce two data models, which are called PDM and WfMS, and explain how to classify the proposed system into them. And then, we will further describe how the back-end three-layered architecture stores the dynamic data type into the database.

**Keywords:** Logistic, Supply Chain Management, SCM, E-Business, Database

### 1. INTRODUCTION

This paper proposed a layered-architecture of database in supply chain management applications. Over the past decade, the rapid advancement in information technology, especially the Internet, has led to the impact of many industries. The Internet environment offers the large flexibility, paperless and 24 hours service to users. As the world-wide-web becomes a popular medium in the human life, people are familiar with the web-based application interface without long time training. While the Internet delivers the large power of coverage, it also provides web tools with the multi-media features.

Supply chain management refers to all the management functions related to the flow of materials from the company's direct suppliers to its direct customers [1,2]. These include ordering, production planning, warehousing, inventory control, packaging and delivery. For example, manufacturing garments will start from purchasing materials from the material supplier, the factory will plan the production material they need. The garments are then shipped to the distributor and finally reach the retailers [3]. The supply chain management involves the collaboration of all members in the entire process.

There are three main scopes that have been considered in our system: information exchange, workflow coordination and flexible logistic routing [4]. The information exchange refers to the information sharing among the supply chain members. The information includes any type of data that could affect other members, such as inventory status, product details and shipping schedules. The workflow coordination refers to the streamlined and automated workflow activities between supply chain members. For example, the manufacture workflow steps involve multiple companies. The time schedule between each step can be tightly coupled, so that collaboration in terms of time, cost and accuracy can be achieved [5]. The flexible

logistic routing refers to find an adaptable and extensible route of the logistic flow of new products. It allows re-structuring the supply chain, such as roles and responsibilities of members, to improve the overall performance. For example, it can be achieved by joining a new partner, inventing a new route of delivery with lower cost or shorter business cycle. These requirements consequently seek for a very generic database schema design, which permits any kind of product data, and logistic information can be stored in the system.

In this paper, we will present our generic supply chain management system, and describe how the system works in terms of information exchange, workflow coordination and flexible logistic route. In Section 2, we introduce the two proposed data models and explain how to classify the proposed system into them. In Section 3, we will describe the design of three-layered database architecture. We will conclude and discuss some current limitations of our approach in Section 4.

### 2. DATA MODEL CLASSIFICATION

In our proposed system, we classify two kind of data model in the supply chain management: Product Data Management (PDM), and Workflow Management System (WfMS) [6]. This two data model can provide the best solution of the information exchange and workflow coordination in the supply chain management. The PDM is used to control access to documented versions of product designs, which include the traditional single data record such as product details, company contact details. It plays an important role of storage and access of the data and documents throughout the process. Conversely WfMS allow managers to coordinate and schedule the activities of supply chain to optimise the flow of information between the resources and the partners. It is used to coordinate the more complex and repeatable work processes of production.

## 2.1 PDM (Product Data Management)

Based on this two data model, the system will prepare a data input and retrieval interface for the access of the logistic information online. Since the PDM is an ideal model to control product and contact information, which involve two kind of database structure design: One entry of table storage and multiple entries of table storage. The one entry of table storage satisfy the table schema which have only one-to-one relation with other tables, and the purpose of this table is only used for storing & accessing the record later. For example, the contact management of the supply chain members, it will normally only have one single table called 'member' to store and access the record. However, the multiple entries of table storage have to handle when one table has been normalized by 3-N rules, resulted in splitting into one-to-many relationship with another table. For example, one invoice will have multiple purchased items details, which establish one-to-many relationship with the entry. Hence the sales management in the retailers or the ordering system from the distributors are belonging to this kind of data input.

## 2.2 WfMS (Workflow Management System)

Conversely, the WfMS category will be more about the time-related task, which can handle any re-structuring, such as roles and responsibilities of all the partners, in the supply chain logistic route. The system can automatically detect the time conflict between partners in the existing route. When the manager arrange for a workflow, which may require the member A, the system will check for the availability of the member A, and wait for guarantee from member A about the delivery in real time. If it has the resource conflicts, the system will inform the user about the next decision.

## 3. THREE -LAYERED ARCHITECTURE

As shown in the data model above, the application database is required to be able to change the internal storage structure and the access medium. For example, most of the permanent storage medium of the Internet application are the tradition RDBMs, by using the forth generation language to access the database. Alternatively the XML file is used as the storage medium, and it is because of the temporary characteristic of the data or the security risk to store the information into holder's database. On the other hand, the fast growing business activities may require the changing of the database structure, like having additional attribute for customer record. The traditional alternation of the database structure will require large processing time to update the database schema. Consequently, we are seeking a system database model to allow the changing of the storage medium, and also change of the database structure. Three-layered model is to aim for this goal, and to provide the adaptability, extensibility and reusability of the business database

structure. The database connection layer maintains the connection between the system program and the database. It also provides the user interface for the access and manipulation. Secondly, the database structure layer is a run time object layer. It is responsible to manage the table schema in the database. Finally, the physical layer handles the traditional storage medium such as the RDBM database and the XML files. With the integrated power of the dynamic structure database in the back-end, it can allow the user to define corresponding functions to access the data in the database. Hence the system can be platform independent, back-end database independent and also structure independent. Besides of the flexibility, it can also support the multi-media data files, as the user can retrieve the data by content. In addition to the collected data, it also can provide a visualization of the information in graphical vision. With the help of the data visualization technique, the user can understand the current large set in a second.

## 4. CONCLUSION

In this paper, we have described our approach to supply chain management system based on the two data model, the PDM and WfMS, and the three layered architecture of the database design. We have successfully introduces a supply chain management system in terms of information exchange, workflow co-ordination and flexible logistic route.

Currently, the proposed system is limited by the access time of the database in the structure layer. It is due to every database operation require access of the database structure before the page is loaded. However, the database structure could be possible to store in the run time object, and which can write back to the database when the object is terminated.

In conclusion, the performance of generic supply chain management is an excellent solution in the supply chain management.

## ABSTRACT

In this paper, we introduce the way of deriving hierarchical structure of a workflow model represented in classical Petri-net, even for the cases with cycles, which allows handling a workflow model efficiently. More specifically, our method identifies any block structures as candidates for the subprocesses and represents them as a single block node in the upper layer of the hierarchical model. The proposed method can make workflow analysis and design more accurate and efficient and further lead to a better design on a collaborate environment.

**Keywords:** Workflow Model, Hierarchical Structuring, Process Abstraction, Hierarchical Petri-Net

## 1. INTRODUCTION

Recently, workflow management technology has shown to be one of the driving tools in accelerating process-oriented applications ([8], [11], [14]). There are typically two stages of workflow management, workflow specification and workflow execution. The former defines a workflow model, and the latter generates workflow instances guided by the workflow model [15]. The objective of workflow modeling is to provide high-level specification of processes that are independent of the implementation intricacies of the target workflow management system [16]. The recent surges of e-business process automation efforts in the corporations worldwide places workflow analysis and design as a fundamental task of more importance and asks for a model capable of easy interpretation and various analyses with efficiency [4].

Petri-nets, a directed bipartite graph with two node types called places and transitions, have been utilized as an effective methodology in system modeling ([6], [13]). The Petri-net models provide clear graphical representation and profound expressiveness for modeling concurrent, qualitative and quantitative properties. Moreover, the availability of various analysis utilities with Petri-nets provides a means to verify and validate a system, thus has made Petri-nets widely applied for analyzing systems in many areas, including workflow models ([3], [4], [7]). However, introducing the states of the system in the model, called places, the process model represented in classical Petri-nets almost doubles the complexity of representation, in number of nodes and arcs, than the activity-based direct graph model representation. This makes it hard to interpret the business processes represented in Petri-nets for the human designers and rare to be employed by commercial workflow management systems.

Hierarchical Petri-nets, as a type of high-level Petri-nets, provide a mean to model complex system in a more manageable way. When to model complex processes, a classical Petri-net is structured hierarchically by

introducing subprocesses, using either a top-down or a bottom-up approach. This divide-and-conquer strategy of dividing a complex process into smaller subprocesses allows overcoming the complexity for further analysis. Furthermore, the identification of subprocesses provides the way of reusing previously defined processes and often makes it possible to model a complex process more quickly ([1], [2]). Although hierarchical decomposition of a complex workflow process is a useful step in workflow analysis and design, until now there has been no reported work of its automated support in the literature. When the process model is complex, it is quite perplexing for a human designer to recognize substructures of potential subprocesses [5].

In this paper, we introduce the way of deriving hierarchical structure of a workflow model represented in classical Petri-nets, even for the cases with cycles, which allows handling workflow model efficiently. More specifically, our method identifies any block structures as candidates for the subprocesses and represents them as a single block node in the upper layer of the hierarchical model. In case of a model with cycles, our method partitions the given model into several acyclic subsets according to feedback structures, and utilizes the resulting partitioned structures when to compose a block. This paper is organized as follows. In section 2, we present the preliminary concepts such as a workflow-net and its hierarchical extension. Section 3 describes the steps of hierarchical structuring for the workflow models represented in classical Petri-nets, with an illustrative example. Section 4 concludes the paper.

## 2. A WORKFLOW-NET AND ITS HIERARCHICAL EXTENSION

### 2.1 Workflow-nets

Petri-nets, represented by a directed bipartite graph in which nodes are either places or transitions, are widely studied and successfully applied in many discrete-event dynamic systems ([6], [13]). Places, represented by circles, describe states or conditions of the system and

transitions, represented in rectangles, describe the events or transactions. The relationships between them are represented by a set of arcs in either direction.

The strong mathematical foundation of Petri-nets and the availability of a wide range of supporting tools have made them popular including workflow domain ([3], [4], [7]). Petri-net-based workflow models represent business logics by a formal but also graphical language. Workflow procedures are specified using a technique with formal semantics of the classical Petri-net and several extensions (color, time, or hierarchy). Availability of abundant analysis techniques [12] is another driving force for the Petri-net-based workflow models. In general, these methodologies can be used to prove properties, like safety, invariance, deadlock, etc., and to calculate performance measures, like response times, waiting times, occupation rates, etc.

A *workflow-net* is a Petri-net-based representation of a workflow process with some syntactical requirements [2]. A workflow process defined in terms of a Petri-net has a single input place *start* and a single output place *end*. And each transition or place should lie on a directed path from *start* to *end*. In other words, there should be no "loose" nodes. Thanks to this requirement, each node can be reached from the place *start* and the place *end* is always reachable from each node, by following a number of arcs. Of all workflow perspectives, e.g., control-flow, data, organization, task, and operation, the control-flow perspective is the most prominent one because it defines the backbone of the workflow on which other perspectives can be specified [4]. Workflow-nets focused on control-flow perspective in modeling a workflow process definition are utilized in this paper.

## 2.2 Hierarchical workflow-nets

Although the Petri-net has many features to model concurrent, qualitative and quantitative properties, the strict representation of a complex business process is hard to read and understand for the human designers. When facing more complicated situations, the classical Petri-nets become too large and inaccessible, or it is not possible to model a particular activity. The high-level Petri-net, extended with color, time, or hierarchy, etc., helps for more close representation of the problem situation, specific with the perspective considered. The high-level Petri-net, inherits all the advantages of the classical Petri-net, such as the graphical and precise nature, the firm mathematical foundation, and abundance of analysis methods [1].

The workflow-nets encountered in practice have many tasks with very complex interaction structures. For the designer of such a workflow the complexity is overwhelming and communication with end-users using one huge diagram is difficult [5]. Hierarchical Petri-net, as a type of high-level Petri-net can help to model complex situations in more structured and accessible way

[1]. A complex workflow can be decomposed into smaller subflows until the desired level of detail is reached. In addition, this mechanism can be utilized for the reuse of existing workflows [5]. Although hierarchical decomposition of a complex workflow process is a useful step in workflow analysis and design, until now there has been no reported work of its automated support in the literature. Next, we explain our approach of identifying and abstracting the blocks of the workflow model as potential subprocesses to make the process more simplified and manageable.

## 3. HIERARCHICAL STRUCTURING OF A WORKFLOW-NET

Hierarchical structuring of a workflow-net by abstraction is used to identify the potential sub processes and to make the original process more manageable. Our workflow abstraction method utilizes the concept of inline blocks. An *inline block* is a subset of nodes and arcs among those nodes that satisfies the blocked transition property [15]. According to the Workflow Management Coalition, the *blocked transition property* states that any *inward transition* to the inline block can only occur to the start node of the block and that any *outward transition* from the inline block can only occur at the end node of the block. An inline block is *reducible* to a *block node* or may be modeled as a sub-process of the original process definition. This helps in managing a large-scale model, including verification of structural conflicts [5], being represented as a hierarchy of simple smaller models. Identifying inline blocks manually from a complex workflow [5] is a difficult task even for an experienced process designer.

### 3.1 Steps of hierarchical structuring

Fig. 1 shows the block diagram of the suggested method for the hierarchical structuring of a workflow model represented in Petri-net. As shown in Fig. 1, our method is comprised of three main steps: 1) Partition a cyclic workflow-net into a set of acyclic substructures; 2) Compose next available candidate blocks; 3) Abstract any block satisfying blocked transition property into a block node.

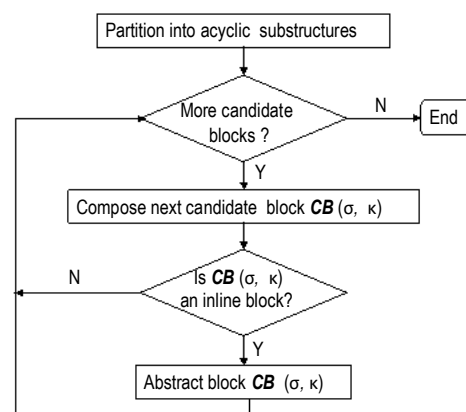

Fig.1. Illustration of the algorithm

### Partitioning a cyclic workflow model into acyclic substructures

Step 1 identifies feedback structures and partitions the given cyclic model into a set of acyclic substructures iteratively, even for the models of nested feedback structures. The rank of each node, utilized in Step 2 when to select the next candidate block, is computed with “back edges” [10] temporarily removed. According to the *order of feedback*, nodes are classified into the so-called *n<sup>th</sup>-order Feedback Nodes*, denoted by *FN*. The *n*-th iteration of Step 1 identifies *FN*, by classifying the set of nodes *N*. The detailed explanation of Step 1 with illustrative examples is given in [9], with a directed graph representation.

### Candidates of inline blocks with cycles

Step 2 first configures potential inline blocks, substructures of the given model, with one of the *Split nodes* (except Feedback Splits) or *Feedback Joins* as the block start node, called the *source*, and one of the *Join nodes* (except Feedback Joins) or *Feedback Splits* as the block end node, called the *sink* [9]. Those potential inline blocks are referred to as *candidate blocks* because they may or may not satisfy the blocked transition property. This initial candidate block, composed with split and join nodes as the border nodes, can be easily extended without further verification effort by adding sequential nodes at the borders. This way of composing candidate blocks can reduce computational cost significantly by focusing on the core candidate blocks.

A candidate block, composed with a node  $\sigma$  as source and another node  $\kappa$  as sink, will be denoted by  $CB(\sigma, \kappa)$ . For convenience, the set of nodes that spans the candidate block  $CB(\sigma, \kappa)$  will be also denoted as  $CB(\sigma, \kappa)$ , without confusion. The algorithm starts with the simplest candidate block and extends to larger ones, iteratively. More specifically, the algorithm starts with  $CB(\sigma, \kappa)$ , with  $\sigma$  as one of the candidate sources of maximum rank and  $\kappa$  as one of the candidate sinks, reachable from  $\sigma$ , of minimum rank. At next iteration, new candidate block is selected by fetching new sink  $\kappa'$  of the next higher rank with the same source  $\sigma$  of the current candidate block; when all candidate blocks with  $\sigma$  as source are evaluated or excluded, The algorithm fetches new source  $\sigma'$  of the next lower rank from the stack of candidate sources and proceeds forward.

### Blocked Transition Property for Cyclic Workflows

Step 3 checks the *blocked transition property* [15], i.e., no disallowed inward and outward arcs should exist for the newly composed candidate block. If the candidate block  $CB(\sigma, \kappa)$  satisfies the blocked transition property, it is abstracted into a new block node, otherwise the proposed method fetches next available candidate block.

In case violations of the blocked transition property happen only at the source or the sink, we can compose an inline block by splitting the source or the sink. Fig. 2 illustrates an example of composing an inline block with  $CB(\sigma, \kappa)$  by splitting both the source  $\sigma$  and the sink  $\kappa$  of  $CB(\sigma, \kappa)$ . Note that if only one of these two violations occur, we can compose an inline block with  $CB(\sigma'', \kappa)$  by splitting the source  $\sigma$ ,  $CB(\sigma, \kappa'')$  by splitting the sink  $\kappa$ . The arc from node A or the arc to node B, where  $A, B \notin CB(\sigma'', \kappa'')$ , does not violate the blocked transition property for the resulting inline block of  $CB(\sigma'', \kappa'')$ . The newly added nodes  $\sigma''$  and  $\kappa''$  in Fig. 2 are null transition of no tasks to perform. The null state nodes  $\sigma'$  and  $\kappa'$  are added to meet the requirements of the Petri-net model, that is nodes should be connected with others of distinct types. Note that it is not necessary the source  $\sigma$  and sink  $\kappa$  are of same node type and is worth for splitting only at the source or at the sink.

Fig. 2. Composing an inline block by splitting the source or the sink

### Types of block structures

According to the node type of the source or the sink, each block structure can be classified into one of the four types that can be reviewed as follows from the Petri-net model perspective:

*Transition-to-Transition block (T-T block) or Place-to-Place block (P-P block)*: The abstracted block node of a subnet, either type of a transition or a state, is connected with distinct type of nodes, and the resulting abstracted model meets the requirement of Petri-net representation. The block structure of any of these types can be represented as a separate subprocess, making the workflow model simpler. When a particular block structure, represented as a subprocess recurs several times in distinct workflow processes, the reuse of this subprocess often makes it possible to model a complex process more quickly.  $CB(\sigma'', \kappa'')$  in Fig. 2 is a T-T block.

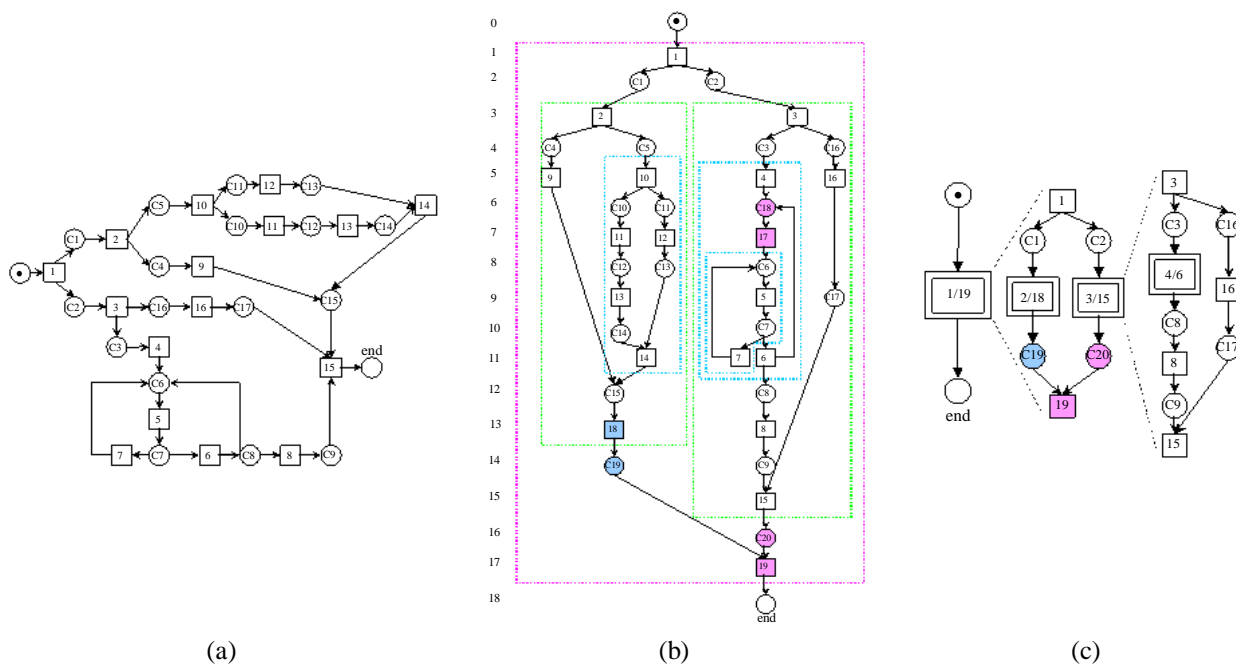

*Transition-to-Place block (T-P block) and Place-to-Transition block (P-T block)*: These types of block structures will make it ambiguous to assess the types of the abstracted block nodes. Moreover, whatever node type is assessed for the abstracted node, the resulting abstracted model, with the abstracted node connected with a node of same type, will not meet the requirements

of the Petri-net representation. To handle these mismatching source-sink block structures, we basically extend these structures by adding a sequential node prior to the source or after the sink. When there exists no such sequential node, our method inserts a pair of new null nodes either before or after these structures and then extends the structure. Our method gives priority to compose the extended block into a *T-T block*, when to insert new pair of nodes, if necessary, and to select a sequential node to add.

### 3.2 An illustrative example

Fig. 3(a) shows an example workflow-net model, of 16 transitions and 17 places, for a process of organizing a

party modified from [2]. Figure 3(b) shows the normalized model with ranks of nodes indicated to the left. Figure 3(b) also shows 6 substructures, indicated by dotted boxes, composing each corresponding block satisfying a blocked transition property. Note that two pairs of nodes (17, C18) and (19, C20) are inserted to split nodes C6 and 15 and to compose the block structures of **CB** (C6, C7) and **CB** (3, 15), respectively. Another pair of nodes (18, C19) is inserted to make the mismatching block of **CB** (2, C15) into a *T-T block* of **CB** (2, 18) extended by adding node 18. Note also that another mismatching block of **CB** (C18, 6) is extended into a *T-T block* of **CB** (4, 6) by adding an existing node 4 before **CB** (C18, 6).

**Fig. 3** (a) The original workflow-net model modified from [2], (b) the normalized model with blocks indicated, and (c) Part of top 3 layers of the resulting hierarchical model of total 5 layers

## 4. CONCLUDING REMARKS

The business processes tend to be more complicated and have more functions according to the needs of the internal and external request. Thus the resulting process models with many transactions and activities are hard to manage. Moreover, enterprises try to make their business processes more extensible to inter-organizational workflow models for the cross-organizational process, requiring several distinct process design teams should work cooperatively.

Though hierarchical decomposition of a business process can help to manage complex situations in more structured and accessible way [1], until now there has been no reported work of its automated support in the literature. In this paper, we introduced the way of hierarchical structuring of a workflow model by detecting and abstracting the block structures as potential

subprocesses to make the given large-scale workflow model more simplified and manageable. Our method is comprised of three main steps: 1) Partition a cyclic workflow-net into a set of acyclic substructures; 2) Compose next available candidate blocks; 3) Abstract any block structures, as candidates for the subprocesses, into a block node in the upper layer of the hierarchical model. Automated support of hierarchical structuring of large-scale enterprise processes will make them more manageable and further lead to a better process design on a collaborate environment.

### ABSTRACT

Manufacturing enterprises in the future will have to survive and develop in the network economy with the development of information and network communication technology, the globalization of economy, and the interaction of these two factors. Nowadays the business environments which manufacturing enterprises are facing are very complicated and volatile. The traditional coordinating relationships between operation models of manufacturing enterprises and their business environment have already been changed as a result of globalization, informatization and personalization of customers' needs. New coordinating relationships are in the process of forming.

Concerning operations management in manufacturing enterprise, traditional management theories and methods only confined to the solving of problems within the boundaries of individual enterprise. The introduction of supply chain management makes people considering enterprise problems in a larger context, but most researchers in this field pay more attention to tactic issues. Typical solutions are methods such as postponed manufacturing, information sharing and interests sharing. The systematic and strategic analysis of the supply chain is ignored.

Systematic analysis approach is adopted in this paper. We start our work from the analysis of environment, objective, and structure of supply chain system. Porter's value chain model is then studied and its limitations under new circumstances are pointed out. On the basis of the work described above, we analyze the features of network economy and explore the new value chain model for manufacturing enterprise in the network economy. Finally an empirical case study is conducted.

**Keywords:** Manufacturing Enterprises, Value Chain, Systematic Analysis, Net Economy, Case Study

### 1. GENERIC MODEL OF MANUFACTURING ENTERPRISE SUPPLY CHAIN SYSTEM

In this part, we analyze the environment, boundary, function, objective and the structural element of supply chain system.

The environment of system includes behavior of competitors, change of customers' demand, change of policy, trend of technological change, supply condition, etc. Enterprise environment is the part that is usually beyond the control of enterprise.

The boundary of system consists of supply boundaries, distribution boundaries and other boundaries between manufacturing enterprise and its partners. In essence, system boundaries are the boundaries of resources and technologies. The resources and technologies within boundaries are those that can be allocated and managed by manufacturing enterprises.

The function of system refers to the abilities to provide satisfactory products and services to the customers through cooperation and coordination among supply chain partners in response to the requirements of market competitions as well as customers' needs with regard to quality, price, delivery and innovation. The functions of system mainly embody the rapidly responsive ability to

meet the needs of customers with low cost.

The structure of system refers to the relatively stable relationships among subsystems or elements within system boundaries. The relationships here are those that form among manufacturing enterprises and their suppliers, distributors and other partners around the activities to provide products and services to meet the needs of customers. These relationships include not only the relationships with regard to the material flow, information flow and cash flow, but also the relationships concerning personnel and organization, technology cooperation, interests allocation, and performance management among different entities.

A system can survive and develop only by adapting its functions and objectives to the changes of environment. The environment of system determines the objectives of system. The objectives of system raise the requirements of system configuration, while the realization of system objectives depends on the structure of system.

### 2. VALUE CHAIN MODEL OF MANUFACTURING ENTERPRISE

Michael E. Porter's value chain model reflects the relationships among the environment, objective and structure of the supply chain system of manufacturing

enterprise within the context of traditional industrial economy.

Porter introduced the concept of value chain in his book entitled *competitive advantage*. As a system model, value chain model mainly has the following connotations:

- ò The competitive environment of enterprise consists of five competitive forces including the entry of competitors, the threat of substitutes, the bargaining power of buyers, the bargaining power of suppliers, and the rivalry among the existing players. The five forces determine the achievement of enterprise objectives.
- ò The objectives of enterprise reflect its abilities to gain profit. Enterprise achieves its objectives through value chain configuration and wide variety of value creating activities. Value chain refers to a collection of different activities including product development, production, marketing and sale, delivery and other supporting activities. Value chain and value creation of the chain reflect the relationship between structure and objectives of the system.
- ò Activities along value chain are closely interconnected. Value creating activities of an enterprise can be categorized into two types - primary activities and supporting activities. Primary activities refer to all kinds of activities that associate with material creation of product, marketing and sale, and after-sale service. Primary activities include inbound logistics, operations, outbound logistics, marketing and sales, and service. Supporting activities support primary activities and provide procurement, technology, human resource and other functions within enterprise to ensure mutual support. Supporting activities include procurement, technology development, human resource management, and infrastructure. The former three supporting activities connect to every primary activities and support entire value chain. Enterprise infrastructure also supports the entire value chain though it does not connect to specific primary activity.

Porter's value chain model has the following features:

- ò Partners such as suppliers, customers and distributors are viewed as rivals.
- ò It is considered that the activities along the value chain should be controlled to prevent the invasion of competitors upon market profits. Vertical integration is adopted as primary approach to realize control.
- ò Production activities are managed as basic value generating part, as a result of the enlargement of production scale and the reduction of production

cost are considered as primary management approach.

### 3. VALUE CHAIN MODEL ANALYSIS WITHIN THE CONTEXT OF NETWORK ECONOMY

The limitations of value chain model of Porter include the following three aspects:

- ò The analysis of environment is simplified. The competition is emphasized while cooperation is ignored.
- ò The recognition about objective is limited. Only the profitability of individual enterprise is taken into account while the identification of customer's needs is ignored, due to the ignorance of the fact that the basis for an enterprise to survive and develop is meeting customers' needs.
- ò The analysis of system structure is limited within enterprise. Dynamic change and interaction, roles of information, innovation and people are ignored.

Therefore, it is necessary to analyze the environment, objective, and structure of the supply chain system of manufacturing enterprises under the new circumstances.

The new environment has the following features:

- ò Globalization. The scopes of competition and resource collocation change from region to the whole world. Division of work and cooperation around the world accelerate the trend of specialization.
- ò Personalization of customers' needs. Mass markets are taken place gradually by segment markets.
- ò The development of information and communication technology infrastructure. Information and communication technology infrastructure provide a platform for inter-enterprise cooperation, making it possible to cut down substantially the management cost within organization and the transactional cost between organizations.

The objective of the existence and the development of supply chain system remains value creating. The value of product is finally determined by customers. It is the measurement of customer satisfaction.

Supply chain is a collection of many enterprises. The factors that can coordinate behavior of different enterprises come from external environment. The most important factor that determines the objective is the needs of final customers. Objective can be denoted as specific output that can meet customers' needs at specific time with specific price and should be comprehensively measured from several aspects including price, time, quality and service.

In order to adapt to the change of environment, manufacturing enterprises should establish new supply chain system structure.

Wide application of information technology is changing the way of communication within and between enterprises, making it possible for enterprises to extend their scope of control and management. At the same time, the trend of specialization around the world has brought about new opportunity for manufacturing enterprises to reconfigure their different kinds of operations activities. For example, procurement, product development and technical service that are previously considered as supporting activities had now become the primary activities that create value for enterprises. Infrastructure that needs lots of investment can be cheaply obtained outside the enterprises.

Under the new circumstances, enterprises can gain profits by establishing tight and diverse relationship with suppliers, customers and other partners. In order to do so, the following two factors are very important. First, enterprises should have their own core competencies, yet it is not necessary to allocate resources on each part of the value chain. Second, enterprises should establish good information infrastructure and international operations platform so as to integrate and make use of resources from all over the world.

The model of relationships between new environment, objective and structure of the supply chain of manufacturing enterprises is shown below.

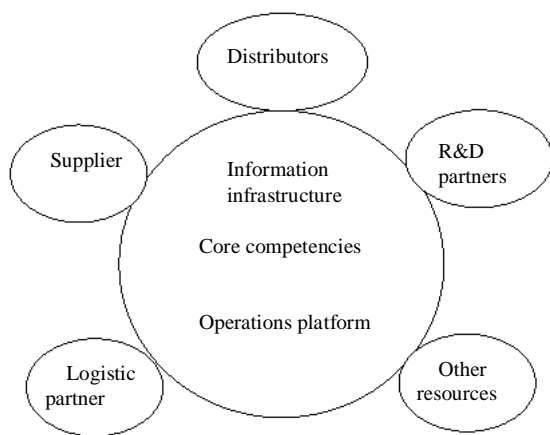

Figure1: Supply Chain System of Manufacturing Enterprises in the Network Economy

#### 4 A CASE STUDY OF BANKING EQUIPMENT MANUFACTURER

##### 4.1 Background of BEM

BEM (a virtual name) specializes in the development, production, sales and after-sale services of ATM (Automatic Teller Machine) equipment whilst engaging in other monetary electronic equipments. With the initial capital of RMB 50 millions and 12,000 square-metered manufacturing center, BEM can roll out

more than 6,000 sets and generate RMB 100 millions as annual sales revenue. BEM is pinning its long-term hope to become a world ATM manufacturer and it already gains its sound position in China.

BEM owns its state-level enterprise technology center where a handful of veterans work together. Blended with its sophisticated management and trustful alliances with well-renowned suppliers at the home and abroad in ATM field, in addition to its combined strengths in modular design and famous brand components, BEM provides tailor-made products and services of superior quality for different kinds of customers.

Currently, BEM is tapping into the fast-growing economic region Guangzhou and strongly penetrates in Southern China. Besides, BEM further moves into seven Chinese regions by launching 19 contact points for its after-sales services. Due to the intensified domestic competition, BEM relentlessly expands its presence in new-fangled international markets, mainly in Asian developing countries such as Philippines, Sudan and India.

##### (1) Tremendous Market Potentials

Automatic Teller Machine (ATM) was a novelty to cash-taking China when first introduced in late 1980s. By some statistics, the United States leads the ranking of ATM installations and its deployment exceeds 1,250 terminals per million. Meanwhile, the deployment rates in HK and worldwide are 410 and 204 per million respectively. With a current base of 50,000 ATMs (or 42 sets per million), the Chinese ATM market has just begun to take shape and its all-out explosive growth will possibly make itself the world largest and juiciest by 2007, as suggested by some experts.

##### (2) Intensive Competition

The hope-fueling China with its untapped potentials has drawn feverish competition amongst a handful of international ATM vendors encompassing NCR Corp., Diebold, Siemens, Fujitsu and Hitachi as well as numerous domestic ones (such as Lide, Guangli and Eastcom) – all vying for a largest piece of pie in Chinese ATM market. Amongst them, the “foreign brands” dominate the market and have grabbed a 90% share, only having slipped the remaining 10% away from their big hands onto their domestic counterparts. BEM controls 70% of domestic brand’s share, making up a 7% of market share in China. Based on the above figures, we still discover that BEM has its dominant position over the domestic brands though its share is obviously small compared with those of international vendors.

##### (3) Critical Success Factors for Industry

With regard to the unique business environment in China, brand image has become one of the principle factors to ensure the ATM success. In fact, those international super-brands including NCR and Diebold,

as opposed to domestic brands, have been identified as superiority in Chinese state-owned banks and are deployed by most of them based on their brand preferences. Besides, product and service quality are considered to be high performance gaps. Furthermore, Guanxi (i.e. interpersonal relationships) connections underpinned by Chinese cultural practices should be singled out as an important instrument in accounting for the business success in China.

Compared with heavyweights, BEM can provide flexible products at reasonable prices. However, it is still a long coming for BEM to develop strong brand equity and highly reliable products for those banking institutions.

#### (4) Operating Performance of BEM

After considerable improvement efforts, BEM has achieved significant performance outcomes in 2003, which are illustrated as below:

- (i) **Gross Output Value of Industry** : RMB 200 millions (+63.3%);
- (ii) **Sales Revenue**: RMB 180 millions (+51.6%);
- (iii) **Profit Growth**: Exceed the Directors' annual target.

#### 4.2 Supply Chain/ Value Chain Model in BEM

World-class supply chain configuration has become a crucial issue in the competitive strategies of ATM manufacturers faced with big propositions of cutting their costs and improving operations efficiency in the ATM field. The paradigm shift toward supply chain excellence has promoted the urgent needs of the BEM to relentlessly improve its supply chains for securing its competitive advantages. In order to understand the current situation of the BEM's supply chain management, we will identify how BEM manages its ***purchasing, inventory, sales and information***, following the discussion on its supply chain structure.

##### (1) The Supply Chain Structure

Before a closer investigation on its supply chain in the four perspectives, we will unveil the ***supply chain structure*** of BEM by demonstrating a simplified web-centric model, which is illustrated as follow Figure 2.

##### (2) Make-or-Buy

The contemporary economic landscape in the ATM field requires BEM to adopt flexible sourcing strategies in terms of the combinations of in-house production (make) and sub-contracting (buy) in the production and assembly levels. BEM has taken considerable steps towards outsourcing for traditional electronic components (such as display and power) in order to maintain flexibility and avoid over-investment.

On the other hand, BEM assembles the components for the modules, card readers, dispensers, receipt printers, journal printers and diagnostic panels by

itself or sometimes by the sub-contractors located in the Pearl Delta Regions.

Figure 2: Supply Chain Structure

##### (3) Supplier Integration

The turbulent Chinese ATM market and ever-demanding banking customers have echoed the needs for ***supplier integration***, a managerial approach to tighten the supply chain in order to cut costs and lead times, as well as to build flexibility. Despite the importance of supplier integration, BEM only assigns the suppliers with the responsibility of assembling the generic components while conducting the QC tests by itself.

##### (4) Inventory

Inventory management is key to optimizing the inbound logistics of BEM, and it is pivotal in the supply chain management. In our section, we put an emphasis on the “inventory structure” and “inventory turnover” of BEM.

First, the ***inventory structure*** of BEM conforms to the industry standard that requires more raw materials than semi- and final- products. Actually, the raw materials contribute to 40% of total inventory in BEM whereas the semi- and final-products take the account of 30% and 30% of total inventory in BEM respectively. Besides, its lead times are 15 to 30 days, much less than the industry level (i.e. 30- 45 days). Second, the ***inventory turnover*** of BEM indicates much room of improvement in BEM because it is 72 days, much greater than the industry level (i.e. 40 days).

Having established good relations with its suppliers, BEM has similar VMI arrangements with some of its suppliers. However, BEM faces a vexed issue of how to improve its inventory levels and financial profile given much cash are buried in the inventory in an attempt to shorten the lead time .Figure 3 illustrates the true VMI:

Figure 3: Revised Replenishment Cycle of Raw Materials

### (5) Sales

Supply chain begins with the sources of supply and ends with the customer consumption; therefore, fulfilling the customer requirements becomes an integral part of supply chain process to achieve operational efficiency and to produce sales.

BEM has broken into the untapped ATM market in China and aggressively dived into scalable domestic banking institutions encompassing four state-owned commercial banks. Because of good relationship with the Agricultural Bank of China, BEM has obtained the bank's aggregate order that accounted for 22% of its total sales in 2003. In order to support its international strategies and achieve its marketing excellence, BEM has developed the domestic and overseas marketing divisions to manage the corresponding customers respectively.

There has little doubt that what ATM customers really want is excellent after-sales service because technical problems would seriously affect the patronage of bank customers (customers' customers). In order to secure a high level of brand loyalty, BEM has developed 27 maintenance centers based on the product distributions. Besides, BEM provides service guarantees to the bank institutions. According to the service guarantee, BEM will deliver the maintenance service within 4 hours and solve the technical problems within 12 hours.

### (6) Information

In facing today's extremely challenging business environment, creating real-time supply chain visibility is becoming very critical for BEM's success in the marketplace. Supply chain visibility refers to the sharing of information to a member within the supply chain, for monitoring, controlling and changing supply chain strategy and operations, from production to delivery (Schoenthaler, 2003). Meanwhile, the challenge of getting the right information to the right person at the right time can be simplified by deploying the appropriate IT applications (Schoenthaler, 2003). Indeed, BEM is only concerned with *the sharing of purchasing and production information with the suppliers* by means of email, telephone and fax. Internet is seldom adopted.

Furthermore, despite the increased expenditure on supply chain integration with the goal of improving customer interaction and reducing inventory costs, BEM

appears lagging behind at the moment given its relatively *low level of information sharing with customers*, resulting in limited collaborative activities such as new product development with customers. Presently, the company relies on fax, phones and emails as major correspondence. It can be understood partly because its customers may perceive impersonal communications a better way to explain their individual needs, and partly because BEM hasn't discovered the tremendous opportunities derived from internet and information technology. BEM should get out of the way of relationships between customers and suppliers while providing a technology-enabled framework for a greater level of integration.

Note: A team from South China University of technology joined the project. We have analyzed the 'AS-IS' of BEM and proposed a 'TO-BE' proposal. The primary solution of the proposal is to reconfigure the previous ERP system and integrate it with customers and suppliers to facilitate process integration and improve information visibility of the supply chain.

## ABSTRACT

This study focuses on inventory strategies of Internet retailers (etailers). The etailer faces options of holding her own inventory or outsourcing through the third party(ies). We assess etailer inventory strategies through mathematical modelling and numerical experiments. When ordering and holding her own stock, the etailer has full control of the order fulfillment process but bears the inventory-related risk. When outsourcing stock, etailer's orders may not get an equal priority as for those of the third party's own. Built upon simple operations research models, the numerical experiments suggest that the etailer is better off relying on others to fulfill orders if her demand (profit margin) is low, but should revert to the strategy of maintaining her own inventory if her sales volume (profit margin) is relatively high. Other factors are also investigated. These findings seem to confirm what are being practised in the industry.

**Keywords:** Electronic Commerce, E-Retailer, Fulfillment, Inventory.

## 1 Introduction

This research focuses on online retailers (*etailers*, hereafter) who engage in the sale of physical goods. In general, the order fulfillment process of such an etailer can be depicted by Figure 1.

Figure 1 Order Fulfillment Process of Online Retailers

As presented in Figure 1, customers will place an order at the etailer's website. Upon receipt of each order, the etailer will confirm whether or not stock is available to fulfill the order. Assuming that inventory is indeed available, the order will be packaged, after which it will be delivered to the customer. In general, each etailer's order fulfillment strategy comprises three primary components: inventory strategy, packaging, and delivery. It is now well understood that the order fulfillment process for etailers is different from that of traditional bricks-and-mortar retailers (*retailers*, hereafter), and the importance of order fulfillment to etailers is widely recognized (see Ricker and Kalakota, 1999).

By operating in virtual space, etailers are presented with new options in their order fulfillment process in terms of their inventory strategy, packaging, as well as delivery decisions:

**Inventory Strategy:** Unlike the traditional retailer, the etailer faces several options in terms of her inventory strategy:

- (i) maintaining her own inventory;
- (ii) maintaining zero inventory, and co-operating with one or more third (3rd)-party suppliers. For each customer order the etailer receives, she turns to one of these suppliers to obtain the exact number of units of the goods required to fulfill the order. These 3rd parties can be manufacturers, wholesalers, and other bricks-and-mortar retailers.
- (iii) a hybrid of (i) and (ii). For instance, an etailer may maintain her own inventory as well as rely on 3rd-party suppliers for supplying the product that she sells through her webstore.

**Packaging:** If the etailer maintains her own inventory, it is most likely that packaging will be performed in-house by the etailer before delivery to customers. However, if she decides not to carry inventory but rely on 3rd-party suppliers to meet customer orders, then there are two alternatives for packaging: (i) the packaging function to be performed by the 3rd-party supplier; or (ii) the etailer continues to perform packaging in-house. In the latter case, after a customer order is received, the etailer turns to one of her 3rd-party suppliers to supply the exact number of units required to fulfill the order. The goods, however, are shipped to the etailer's site for packaging before they are finally delivered to the etailer's customer. This arrangement is currently being adopted by Amazon.com, to maintain quality control over packaging and shipping of products. This is especially so when multiple product types are sourced from different 3rd parties.

**Delivery:** There are a number of options: the delivery function can either be undertaken by the etailer her-

self, or she may choose to engage a 3rd-party logistics provider (3PL) to perform the function. The etailer, however, also has the option not to deliver the order to the customer's site. Instead, the order can be delivered to a particular outlet, so that the customer who places the order can pick it up from that site. All of these options appear to be adopted in the etailing industry.

This paper will evaluate, using a combination of mathematical modelling and numerical experiments, the first two basic inventory strategy options open to online retailers. The third option is more complex, and we leave it for future research. The first two options are further broken down into three cases as follows: the etailer

**Case 0:** maintains her own inventory; or

**Case 1:** maintains zero inventory but co-operates with one retailer or

**Case 2:** maintains zero inventory but co-operates with two or more retailers who normally have their own customers in addition to the etailer's. For each customer order the etailer receives, she turns to a retailer to fulfill the order.

Examples of etailers practicing models of Cases 1 and 2 are Zappos.com and Spun.com. Zappos.com sells shoes online and orders are delivered directly from manufacturers' or distributors' warehouses. In some seasons, Zappos.com ships customer orders (via UPS) free of charge. Spun.com sells CD/DVD but holds no inventory. It allies with the wholesaler Alliance Entertainment Corp. which stocks the CDs/DVDs and ships them directly to Spun.com's customers with Spun.com's labels on the packages.

In this paper, we will focus our analysis on the above three cases. Under a given set of conditions, a mathematical model based on dynamic programming will be used to derive the expected profit for the etailer as well as all 3rd-party suppliers. We will compare the above three strategies from the etailer's viewpoint, using profitability as the basis for comparison. Numerical experiments will be conducted to determine conditions under which the etailer will be better off holding her own inventory, as compared to relying on the inventories of 3rd parties to fulfill her customer orders.

Based on the numerical experiments, we will also provide insights on key factors affecting the etailers' decision on inventory strategy. Such insights allow us to explain why major online retailers such as Amazon.com are deviating from their original strategy of zero inventory to the present decision to invest extensively in warehousing, from a purely inventory management point of view. The model also provides a framework for etailer startups or existing etailers to evaluate their inventory strategies.

The close global attention directed towards the development of electronic commerce has resulted in the proliferation of published information on this area. Numerous publications on all aspects of e-commerce appear every-

day, and surveys are actively conducted by numerous agencies. Academic-oriented journals dedicated to the subject of e-commerce include the *International Journal of Electronic Commerce* and *Journal of Organizational Computing and Electronic Commerce*. The academic-oriented research on electronic commerce to-date, however, is qualitative in nature and none of them has directly addressed issues related to the order fulfillment process of etailing. The literature to-date focuses largely on the marketing, information technology, and overall growth aspects of Internet retailing (e.g., Lei and Robey, 1999). Here we only briefly review those that are mostly related studies, and the reader can find a more comprehensive survey in Chen, Hum and Sim (2002).

In essence, our business model of outsourcing inventory by etailers is similar to the term of drop-shipping used in the marketing literature. However, the potential for drop-shipping has been deemed limited in many earlier marketing books (e.g., Scheel, 1990) until the recent Internet era, since the latter has made possible real-time data integration with the physical concept of drop-shipping the goods by third parties directly to the customers. In fact, as pointed out in a parallel work by Netessine and Rudy (2000) on supply chain structures incorporating drop-shipping, an Etailing World survey of internet retailers show that 30.6% of Internet-only retailers use drop-shipping as a primary mode of order fulfillment. Netessine and Rudy focus, however, on Internet-based supply chain structures, comparing and evaluating coordination schemes for such chains rather than on the operational aspect of inventory management of etailers.

Despite the explosive growth of information on e-commerce in general and Internet retailing in particular, it can be seen from the above literature review that currently there is not much literature which addresses the order fulfillment issues of online retailers through mathematical modelling. This paper therefore seeks to make a contribution by sketching out the operational issues involved in the order fulfillment process, and then focusing on one particular issue for a start, namely that of inventory decisions for the online retailer. The inventory literature related to the mathematical model(s) to be used in this study will be detailed in Section ??.

The rest of the paper is organized as follows. The mathematical model to assess the various inventory strategies of an etailer will be sketched in Section 2, and numerical experiments and analysis will be reported in Section 3. The summary conclusions of this study will be presented in Section 4.

## 2 Models

In this study, we will consider a single product, newsvendor type situation. For any retailer (etailer) who holds inventory, orders placed by him (her) will arrive at the beginning of the finite sales season, and there will be no additional replenishment during the season. Such a sce-

nario is representative of many real-life situations such as in the cases of news vendors, booksellers, and other seasonal products, which are all equally applicable to etailing.

Besides physical retailers, independent 3rd-party suppliers for Case 1 may also be manufacturers, wholesalers, or distributors. In general, there are more physical retailers than wholesalers for any given product in any part of the world. As such, co-operating with bricks-and-mortar retailers gives the etailer the opportunity to gain an extensive network of geographically-dispersed stocking points near her customers, without having to set up her own warehousing infrastructure. The potential benefits of such an arrangement to the etailer are obvious: lower delivery costs and shorter delivery lead-time with minimum investments in warehousing and distribution infrastructure.

One of the major concerns of such an arrangement, however, is that retailers tend to give priority to their own customers (including their own online customers). In general, retailers' own customer orders are easier to handle, while those from the etailer are normally small and arrive more frequently and hence more troublesome to fulfill. Because of this, even manufacturers, wholesalers, and distributors may not be so responsive to etailers' orders as to physical retailers'.

Clearly, when a retailer agrees to co-operate with an etailer as in Case 1, both parties would have agreed on some form of "profit sharing" arrangement. For instance, the retailer could give the etailer a discount off his normal retail price for every order he receives from his online counterpart. Hence, by agreeing to co-operate with the etailer, the physical retailer effectively enters into a situation whereby he faces two classes of demand: those from his own customers (the high-profit customers) and those of the etailer (the low-profit ones). If the physical retailer's shortage cost for failing to fulfill his electronic counterpart's orders is less than the shortage cost to his own direct customers, any retailer who seeks to maximize his own profit will naturally find it more attractive to sell to his own customers rather than those of the etailer.

When replenishment is not possible during the sales season, whenever the physical retailer receives an order from his online partner, he faces the decision of whether to satisfy the demand or reject it so as to reserve his limited pool of inventory in the hope that there will be demand from his own customers later on. Given such a situation, the online retailer - who does not have control over the physical retailers' stocking policies - becomes vulnerable and her reliability to her own customers may very likely suffer.

For Case 2, we first consider the option of outsourcing to only two retailers, and then extend the analysis to the case of "infinitely" many retailers. This last special model will provide an upper bound on all outsourcing strategies in terms of profitability. Such retailers can be upstream suppliers as well, such as manufacturers, distributors, wholesalers, etc, who hold inventory. Sim-

ilarly, these upstream suppliers also tend to give higher priority to demands from other sources, such as those from their own on-line operations and bulk orders from other retailers. Nevertheless, our modelling approach and numerical results are also applicable even when 3rd-party suppliers give etailers' orders an equal priority, in terms of order fulfillment from their inventory.

We describe the above structural scenarios because in the lesser developed economies, many retailers are not ready to sell through the internet. In such a context, an etailer comes onto the scene to capitalize on the existing network of physical retailing outlets and therefore enter into alliances with these retailers in the manner highlighted above. Also, because of the lack of ready transportation for the individual consumer, the etailer is able to reach a market not often available to a given retailer. Because of this, retailers are willing to link up with the etailer.

As detailed in Section ??, besides inventory strategy, the etailer order fulfillment process comprises two other key elements: packaging and delivery. In this study, we assume that the etailer will let a 3rd party perform packaging and delivery functions in all three cases. The cost of packaging and delivery will be borne by buyers (as in Amazon.com which charges customers for these costs). To make the analysis as simple as possible, we ignore fixed-investment related costs such as rent/warehousing, IT, etc. Nonetheless, the assessment method to be developed here gives the etailer a guide as to the amount of fixed investment (as well as how much packaging/shipping costs) she can afford to absorb.

The further general assumptions made for all three cases are as follows:

- (i) For conciseness, we assume the sales season is divided into time intervals so short that the probability of more than one customer arriving in any interval is negligible.
- (ii) The probabilistic rule governing the arrival patterns of all customer types is assumed to be known, and every arrival will result in an order of one unit only.
- (iii) Initial inventory is zero and backlogging is not permitted - unmet demand will be lost. (This is the scenario we chose to model initially for this study).
- (iv) Demands for retailer(s) and the etailer are independent of each other. (In some context, as indicated earlier where accessibility to a given retailer is limited, this assumption may be reasonable).
- (v) Holding cost is incurred for all units unsold at the end of the sales season; if it is negative, then it represents the net salvage value.
- (vi) The prices charged to consumers by the etailer and each physical retailer are constant and known.
- (vii) The cost of goods, regardless of whether it is incurred by the etailer or any of the retailers, is constant and known for any order quantity.

- (viii) The sales season is short, such that the time value of money is negligible.

In Chen et al. (2002), we have formulated all mathematical models for all the cases with the above assumptions. These models turn out to be close the model that deals with optimal rationing policies by Gerchak, Parlar and Yee (1985, GPY hereafter). GPY consider a situation in which two distinct classes of customers with different per unit profit contributions exist for a single product or service in a fixed, finite sales season. The main objective of their study is to derive optimal rationing policies at any time (i.e., whether to reject those “low-revenue customers” upon arrival) depending on the number of units on hand and time left until the end of the sales season.

The model by GPY assumes that every arrival will result in an order of one unit only (as we do here). Banerjee and Viswanathan (1989) extend the study of GPY by considering Poisson batch-sized demand. They demonstrate using numerical examples that there does not exist a simple optimal rationing policy. According to McGill and Van Ryzin (1999), the model with batch demand under the yield/revenue management context remains an open problem. The models addressed in the revenue management literature are generally more complicated as they deal with both optimal pricing and inventory allocation among multiple classes of demands. However, that literature typically assumes the total number of inventory units is fixed.

### 3 Numerical Experiments and Discussions

The objective of the numerical experiments is to assess and compare the profitability of the etailer under each of the three cases detailed in Section 2.

#### Steps Taken in the Numerical Experiments

Adopting all the assumptions spelt out in this paper, we assess the three cases at different levels of all key parameters in the model. They include:

- Demand rate: we will assess the impact on all parties' profitability when the etailer's demand is significantly higher/lower than that of the retailers.
- Profit margin: we will change per unit product cost to evaluate the impact of profit margin and vary the “commission” rate that the physical retailer(s) gives to the etailer to see the relative impact of profit margins.
- Holding cost: the optimal ordering quantity is influenced by the holding cost.

- Shortage cost incurred by retailer(s) in failing to fulfill the etailer's order: this affects the retailer's rejection decision and subsequently the profitability of both parties.

We compare how each of the cases performs under different scenarios.

**Brief Summary:** Three key insights have been drawn from the modelling work and experiments. First, the numerical results suggest that the online retailer is better off relying on others to fulfill her orders when she faces small demand in the market (when her demand is relatively low compared to the physical retailers). When she forms alliances with 3rd party(ies), she should go with more than one supplier. As the online retailer's sales volume becomes sufficiently large, she should revert to the strategy of maintaining her own inventory. With a high demand, the risk of having unsold units at the end of the selling season decreases. Also, by carrying her own inventory, the online retailer is able to enjoy a higher profit margin for every unit she sells, since she no longer needs to share the profit with 3rd parties as in the case of relying on others to fulfill her customer demand.

Second, when the profit margin is relatively large and retailers offer deep discounts to the etailer, the latter would be better off by outsourcing order fulfillment rather than holding her own inventory to meet orders. Third, with regard to holding cost, the outsourcing strategy will be attractive to the etailer if the holding cost is relatively high. Several outsourcing strategies were evaluated numerically based on heuristic solutions.

These findings confirm the general trends we observe in the real world of online retailing. For instance, major etailer Amazon.com started off with the strategy of zero inventory and heavy reliance on 3rd parties for order fulfillment. But as the online bookseller's business grew, it deviated from this original strategy to one that involves extensive investments on warehousing and distribution infrastructures. Though many other factors may account for their strategic direction and practices, one cannot underestimate the underlying driving forces highlighted in this study. In another example, a MOR (maintenance, operations and repair) B2B etailer AsiaEC.com holds stocks of office furniture and PC related product categories, while it outsources other products to wholesalers and other MOR stores.

**Further Managerial Implications:** As an etailer's business grows, the option of holding her own inventory becomes increasingly attractive. But instead of investing in his own inventory, the online retailer can consider the option of adopting Vendor Managed Inventory (VMI) program, which has been receiving close attention in the physical retailing scene during recent years. Under VMI, the etailer does not take ownership of the inventory until it is sold.

But regardless of whether the online retailer adopts VMI or decides to invest in his own inventory, warehousing

and distribution are still essential components of the etailer's fulfillment process. The etailer, however, may subcontract this function to a 3PL. Some of the US trucking and logistics firms, such as Schneider National, are building dedicated business-to-business e-commerce fulfillment operations. When a buyer clicks on the "ship now" button on paperloop.com, a bulk paper distributor, the order goes directly to Schneider, which fills it from its own warehouses onto its own trucks.

Clearly, the etailer can undertake a combined strategy of adopting VMI and engaging a 3PL for its warehousing management and distribution functions. By undertaking this combined strategy, the online retailer thereby frees himself once again to concentrate on the core activity of developing the online business.

## 4 Concluding Remarks

We have confined the analysis of inventory strategy within the context of standard inventory costs, and other factors such as packaging, competition, multiple items and order consolidation, gaming, and fixed investments have not been touched in this study. Clearly, these suggest further research possibilities.

In our model, the hybrid inventory strategy of both holding and outsourcing inventory is not addressed. This is alike the inventory transshipment model, and therefore, the literature on transshipment models may serve as an excellent starting point (see Rudi, Kapur and Pyke, 1998, for this). This paper considers inventory decisions, and the models developed in this study permit systematic evaluation of various options.

The demands among retailers (including the etailer) have been assumed independent of each other. While we have indicated possible scenarios where this assumption may be reasonable, it is clearly appealing to extend the analysis to the case where demands among retailer(s) and the etailer are interdependent or that demand cannibalization exists. However, this calls for a substantially different modelling approach as the current model is incapable of handling the demand correlation.

As our models are based on the assumption that no more than one unit of demand arrives at any time interval, an interesting area for future research is to consider batch arrivals. For instance, if a batch order is placed by the online retailer, should the physical retailer reject the entire batch order or fulfill it partially? Also, does it make sense for the online retailer to allow the physical retailer to fulfill the order partially if the batch order originates from a single customer? Finally, if the online retailer does not allow partial fulfillment of orders, will the physical retailer be better off accepting the batch order at the expense of rejecting his own direct customers? Though some of these issues are not unique to the Internet context (e.g., also raised in GPY), they are interesting issues which future research may wish to address.

To ensure a reliable supply, the etailer may resort to other leverages such as commitment contracts with 3rd parties. One scenario would be that the etailer commits to a minimum quantity and the 3rd party guarantees a minimum service level. The research along this line is under way.

Quite clearly, this study is aimed at delineating the issues involved in the entire online order fulfillment process, and our focus on inventory decisions is just a first modelling-based attempt at contributing to this new and rich area of research.

## ABSTRACT

This paper proposes to make On-Demand business process integration based on intelligent Web Services. Business processes are modeled with BPEL4WS. They are incorporated into intelligent Web Services as their knowledge. Implementation framework and techniques are presented. A case of online auction is developed to demonstrate these concepts.

**Keywords:** on-demand business, process template, intelligent Web Service, BPEL4WS, online auction

## 1. INTRODUCTION

Businesses are becoming customer-centric from product-oriented. Enterprises have to respond with speed to customer demands, market opportunities or external threats. They therefore develop their e-Business systems to be more responsive, variable and resilient, i.e., on demand. To this end, their electronic business processes are required to integrate end-to-end across the company and with key partners, suppliers and customers. Service-oriented architecture (SOA) provides a competent computation environment for enterprises to integrate their applications and become on demand. Businesses can become flexible through integration of people, processes and information within and beyond enterprises. SOA and standardized Web services technologies make it possible to simplify information systems through automation and virtualization, enable access to and create a consolidated, logical view of resources across a network. Every application and resource is represented as a service with a standard interface which simplifies its activation and the exchange of information. Enterprises can treat business processes and the underlying infrastructure as defined components that can be mixed and matched at will. <sup>[4, 5]</sup>

To this end, numerous research efforts have been put on SOA based business process integration. This paper describes process template-based business integration, which is an ongoing research at IBM Watson Research Centre. We locate characteristics and advantages of template-based on-demand business, and try to improve it with intelligent Web services, which was proposed and studied in our previous publications. <sup>[1]</sup> The proposed intelligent Web services incorporate possible business processes, which are modeled with BPEL4WS, into its knowledge. They run as composition services and flexible business adapters in SOA-based application integration environments. The knowledge makes them rational to response to on-demand business or transaction requests with appropriate processes and call appropriate services. This will be demonstrated through a case study

of online auction for e-Marketplaces, in which an auction service is implemented with intelligence and can instantiate an appropriate process based on the requester's inputs, to accomplish an auction session.

## 2. TEMPLATE-BASED ON-DEMAND BUSINESS INTEGRATION

Today's e-business systems have been found with several drawbacks. An e-Business solution is usually created for a single enterprise, not flexible for an extended business. Systems of suppliers, manufacturers, sellers and customers are all developed with different technologies, running on different platforms. It is very difficult and costly when integrating systems of the whole supply chain. Also, it is not able to handle changes quickly and effectively when being required to meet requirements by another enterprise because business processes are buried in program codes. When processes changes, all these codes have to change. This is time-consuming and may lead to loss of potential business opportunities. Under on-demand business environment, all system components are services, and the whole system is constructed with service-oriented architecture. Some basic services are provided by platforms and service providers, while other business specific ones are created by enterprises own. That is, enterprises only need to focus on their business issues. We can create e-business solution by developing service components and defining templates to integrate these services. With this method, we can integrate e-business systems of different partners and create business solutions easily. When defining templates, business partners across supply chain are all incorporated. As long as they provide corresponding services, business process can be easily integrated with fewer costs than before. All these services and templates are reusable components. Moreover, business processes are no longer buried in codes. We rewrite those templates rather than the entire application to meet process changes.

In template-based on-demand business integration, there

are two concepts with particular importance, which are services and templates. Services comprise of business services and IT services. Business services can be further categorized into four types: demand services, such as sales; supply services, such as logistics; administrative services, such as human resource; control services, such as finance. IT services also have four categories: adapter services, such as data adapter; composition services, such as process flow; platform services, such as messaging; common services, such as authentication and authorization. Among these services, some can be found at service providers, while others need to be developed by enterprises. [2, 3]

When enterprises have all service components for e-business systems, they define business templates to compose those services into business processes and applications. Templates describe how services work with each other and how business processes execute. Composition services are used to integrate other services according to templates. Figure 1 depicts the framework of e-business solution using services and templates.

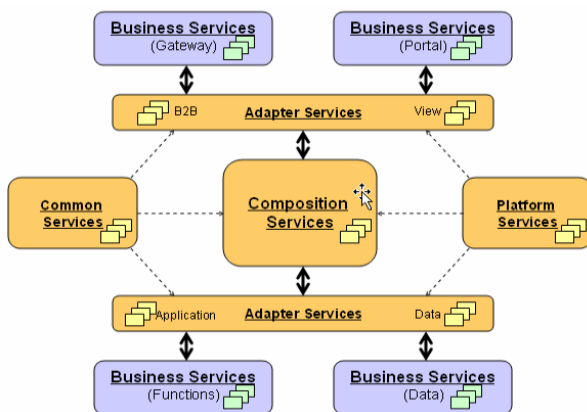

Figure 1. Framework of e-business solution using services and templates [2, 3]

In this framework, business services provide business functions. Common services and platform services provide facilities required by every application. Adapter services facilitate interaction between business services by providing agreed interfaces for them. And composition services integrate all the services above to form process templates and e-business system.

Template-based e-business solution has following advantages:

1. Process templates are independent of technologies and platforms. Changes in them will not impact existing system.
2. Templates and services are all individual artifacts which can be stored and reused later;
3. Templates and services are conformed to standard interfaces. They can be reassembled and reconfigured on demand.

While creating e-business solutions using process templates, we first identify required business services

and IT services. Secondly we search service directory for desired services. We hire them if existed. Otherwise we have to create by our own or request them from other sources. The following step is to define business templates according to business processes, which integrate the services above. Finally, we use these templates to accomplish service composition and create complete e-business solution. The following figure delineates the entire process.

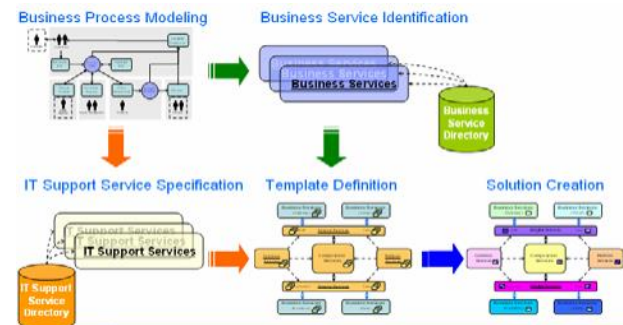

Figure 2. Building e-business solution through template and composition [2, 3]

When business process changes, enterprise only need to develop new service components and define new templates. New application can be easily integrated. Compared to rewriting the whole application, this template-based method reduces cost and makes enterprises more responsive.

### 3. PROCESS MODELING BASED ON INTELLIGENT WEB SERVICE AND BPEL4WS

More and more enterprises are accepting web-based e-business systems. Web services have been envisioned to be one of the key integration technologies. We have enhanced Web services with intelligence-enabled internal model. Semantic Web Service technologies have not been mature enough to represent knowledge. [8] We therefore incorporate well-developed agent knowledge representation model with Web services internal entities. Such intelligent Web services can contribute to the process composition automation, as well as interaction with partners' systems within on demand business solutions.

BPEL4WS (Business Process Execution Language for Web Service) is an XML-based language used to integrate Web Services to model process. [10] That is, it creates templates to compose Web Services. What created by BPEL4WS could also be a Web Service and described by WSDL. BPEL4WS defined how Web Services involved in the process cooperate and interact with each other to achieve business Goals. To implement on-demand business, we can define several business processes using BPEL4WS, and a composition Web Service will use these templates to invoke other Web Services to accomplish the whole business. Such composition Web Service is implemented using

intelligence and has several business processes modeled with BPEL4WS as its knowledge. It chooses the most appropriate process according to external events (e.g. user request) and internal rules, and executes the selected processes to realize on-demand business. Figure 3 illustrates the architecture of process modeling based on intelligent Web Service and BPEL4WS.

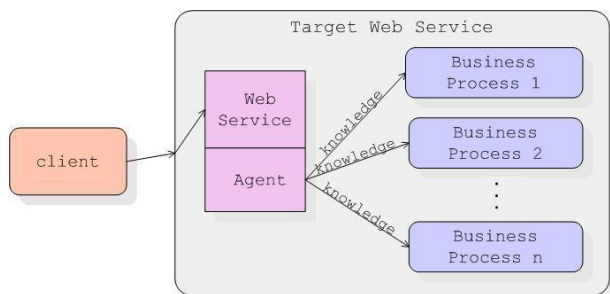

Figure 3. Architecture of process modeling based on intelligent Web Service and BPEL4WS

An end user issues business request through its client software ("client" in above figure), which sends this request to "Target Web Service". "Target Web Service" is implemented with intelligence. It is developed as a software agent with standard Web Service interfaces. With this paradigm, the intelligent Web service can use its own knowledge representation model to incorporate business processes described by BPEL4WS as its knowledge, and then choose the most appropriate one to execute on environment changes and its intelligence. In above figure, from "Business 1" to "Business n" are all represented as agent-applicable knowledge.

#### 4. IMPLEMENTATION ISSUES

For the mentioned case, we use software agent which conforms to FIPA (Foundation for Intelligent Physical Agents) standards to develop intelligent Web service.<sup>[11]</sup> The services are implemented as agents and published as Web Services. FIPA agent uses ACL (Agent Communication Language) for communication, which is not compatible with Web Service's communication protocol, SOAP. When using agent to implement Web Service, we must address this discrimination in communication, that is, to make agent understand SOAP. There are two solutions to this problem:

1. Enhance FIPA agent and make it understand SOAP. With this method, agent can communicate with each other using both ACL and SOAP. But it is too difficult since it is almost the same as developing one specific FIPA agent implementation. In addition to difference in communication protocol, which means we have to add parsing and encapsulating of SOAP to agent functions, communication styles also differ. Web Services support synchronous and asynchronous invocation, while FIPA agent can only be called asynchronously. This adds a great deal to the complexity of this method and finally make we give it up.
2. Add a mediator module for FIPA agent, which can

understand both ACL and SOAP. The mediator receives SOAP message from client, extracts request parameters, creates new ACL message, then puts those parameters into new message and finally, sends ACL message to agent. When agent receives ACL message, it uses built-in parameters to perform requested tasks and returns result to the mediator. On receiving ACL-based result, mediator performs another message format translation and sends SOAP-based result back to client. Then one transaction completes. This method is much easier to implement than the previous one. So it is chosen in this paper.

With regard to how to incorporate BPEL4WS-based business process as agent's knowledge, there are also two considerations:

1. Store BPEL4WS files, WSDL files and other assisting files somewhere FIPA agent can access (e.g. file system). When agent activates, it will go to the specified place, read those files and execute processes described in them. On doing so, it is required that agents must understand BPEL4WS and WSDL, as well as perform corresponding operations. Actually, it means adding BPEL4WS engine to agent, which is even more difficult than adding SOAP engine to agent. So it is discarded.
2. Make use of existing BPEL4WS engine and combine it with agent in some way. We choose to deploy BPEL4WS processes on BPEL4WS server and publish as Web Services. Then agent is able to invoke these Web Services with standard interface, as well as accomplish business tasks. When compared to previous one, this method is more convenient and flexible. Therefore, it is the better choice.

#### 5. CASE STUDY: ONLINE AUCTION

For case study, we use the proposed architecture to implement an online auction business process. Customers can issue an auction request on client interface. Then the request is sent to the auction Web service. The service has a few BPEL4WS business templates as its knowledge and knows which one to choose. Then the service invokes the most appropriate BPEL4WS Web service. The selected process is instantiated as an auction session.

Following demonstrate those two business processes involved. One is called "OnlineAuction" and the other "OnlineAuction2". These two processes are identical in the first four steps, described as follows:

1. Customer logins into auction web site, and then enters information about auctioned commodity and criteria used later to evaluate auction result.
2. Auction mediator receives such information and asks buyers to bid.
3. In this case there are two buyers. On receiving auction request, they will bid separately based on the

information customer entered.

4. Auction mediator collects prices from all buyers, calculates their scores, and determines a winner.

In “OnlineAuction”, the step 5 is:

5. Auction mediator returns price and score of winner to customer.

In “OnlineAuction2”, the step 5 is:

6. Auction mediator returns prices and scores of all buyers to customer, and then suggests a winner.

The differences between the two processes are that “OnlineAuction” only returns information about the winner; therefore auction decision is made by the mediator. While in “OnlineAuction2”, mediator returns information about all buyers and suggests a winner, but final decision is still up to the customer.

In this case, we choose a FIPA agent implementation, JADE (Java Agent Development Framework) to develop intelligent Web services.<sup>[9]</sup> In order to do so, we also use an open source project called “Wsag”.<sup>[6]</sup> It acts as a mediator between the Web Service and JADE agent and makes message format translation. “Wsag” is deployed on Apache Tomcat 4.1.24, while agent is running in JADE 3.1 environment. When publishing BEPL4WS processes as Web Services, we choose an existing BEPL4WS engine, BEPL4WS server 2.0 from collaxa.<sup>[7]</sup>

The following figure illustrates architecture of online auction case.

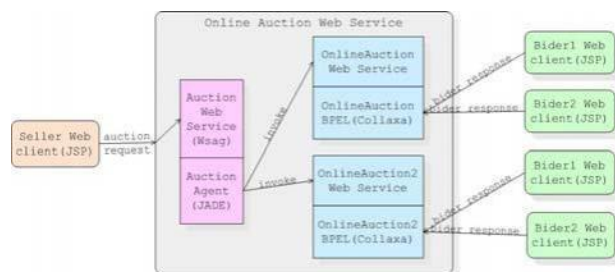

Figure 4. Architecture of online auction case

Following is a complete instance of online auction case. Customer visits auction web site (<http://10.89.103.1:8080/wsag/OnlineAuctionWebClient.jsp>), enters name and description about commodity to be auctioned and specifies weights for buyer's price and reputation. The customer has to choose whether he wants to see bid information of all the buyers or only the winner. In this instance, “Name” and “Description” are set to “Astrology Mythology” and “A Very Interesting Astrology Book”, separately. The weight for “Price” and “Reputation” is 10:1. At last, “Only Return Final Result” is selected, i.e., the customer only wants to see bid information of the winner. This customer request is sent to Auction Web Service, which is implemented with agent and uses “Wsag” as mediator. Auction Agent which accomplishes actual business function is running

on another computer (auction0@SSC036:1099/JADE@<http://10.89.103.36:7778/acc>). When the agent receives request, it knows which process to invoke. If “Only Return Final Result” is selected in this instance, it will invoke OnlineAuction Web Service; otherwise OnlineAuction2 Web Service is called. These two Web Services are implemented with BEPL4WS and deployed on BEPL4WS server running on a third computer (<http://10.89.150.150:9700/collaxa/default/OnlineAuction> and <http://10.89.150.150:9700/collaxa/default/OnlineAuction2>). As aforementioned, these two processes involve human interactions. Buyers can login to web site to participate in these processes (<http://10.89.150.150:9700/OnlineAuctionUI/> and <http://10.89.150.150:9700/OnlineAuction2UI/>). A buyer named “bider1@software” has already login to OnlineAuction web site and sees all process instances waiting for his participation. Then he can examine information of auctioned commodity and criteria, as well as offer price and reputation. After collecting bids from all the buyers, process instance can go on. When calculating scores, process uses following formula:

$$\text{Score} = \text{Price} * \text{PriceWeight} + \text{Reputation} * \text{ReputationWeight} \quad (1)$$

The buyer with the highest score is the winner. Then process will return information of the winner to customer. If customer doesn't choose “Only Return Final Result” at the beginning, process will return information of all the buyers and suggest a winner. Figure 5 shows snapshots for this auction instance.

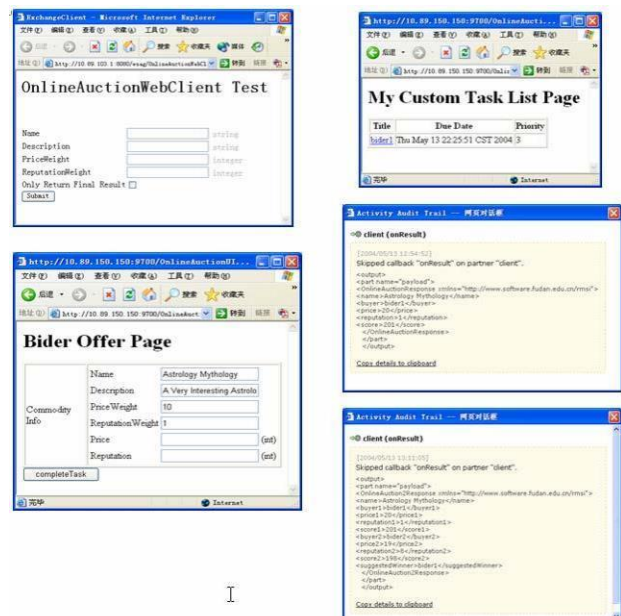

Figure 5. One instance of online auction

In this case, our proposed architecture has been proven feasible. However, Web Service's intelligence is not exploited enough. This needs to be improved.

## 6. CONCLUSION

This paper proposes that business processes modeled

with BPEL4WS can be made part of intelligence Web service's knowledge to accomplish process modeling, as well as on-demand businesses. Several critical issues have been addressed, including system architecture, how to implement intelligent Web Service with agent-oriented knowledge, and how to represent BPEL4WS processes as knowledge. However, there are several issues that still need improvement, i.e., intelligent Web services themselves don't understand BPEL4WS without existing BPEL4WS engine, and we have not utilized intelligence well to make Web Service intelligent. These problems call for research efforts.

# A Two Phase Verification Algorithm for Cyclic Workflow Graphs

Yongsun Choi

Dept. of Systems Management & Engineering, Inje University, Kimhae, 621-749, Korea  
yschoi@inje.ac.kr

## ABSTRACT

The widespread automation of e-business processes has made workflow analysis and design an integral part of information management. Graph-based workflow models enables depicting complex processes in a fairly compact form. This free form, on the other hand, can yield models that may fail depending on the judgment of the modeler and create modeling situations that cannot be executed or will behave in a manner not expected by the modeler. Further, cycles in workflow models needed for purposes of rework and information feedback increase the complexity of workflow analysis. This paper presents a novel method of partitioning a cyclic workflow process, represented in a directed graph, into a set of acyclic subgraphs. This allows a cyclic workflow model to be analyzed further with several smaller subflows, which are all acyclic. As a convincing example, we present two-phased verification of structural conflicts in workflow models for those incurred from the inappropriate composition of partitioned flows and the others within each acyclic subgraph, which is much easier to comprehend and verify individually than the whole workflow model, in general.

**Keywords:** workflow model, directed graph, feedback, partition, verification

## 1. INTRODUCTION

The recent surge of e-business research and development has resulted in the automation of thousands of business processes by means of workflow management systems (WfMS), both within and across corporate boundaries ([5], [7], [9], [16], [18], [30], [32]). WfMS enable the design, analysis, optimization, and execution of business processes. The basic WfMS functions include the separation between the business process logic and business applications, management of relationships among process participants, integration of internal and external process resources, and monitoring and control of process performances ([24], [34], [35]). There are typically two stages of workflow management, workflow specification and workflow execution. The former defines a workflow model, and the latter generates workflow instances guided by the workflow model.

A workflow model (also called workflow definition) consists of a set of activities and their execution sequences, the start and termination of the process, and the resources needed for executing individual activities, such as participants, associated IT applications, and data ([34], [35]). The objective of workflow modeling is to provide high-level specification of processes that are independent of the implementation intricacies of the target workflow management system ([8], [13], [18], [21], [22], [35]). Of all workflow perspectives, e.g., control-flow, data, organization, task, and operation, the control-flow perspective is the most prominent one because it defines the backbone of the workflow on which other perspectives can be specified [1].

Workflow models must be correctly defined before being deployed in a workflow management system to avoid any costly maintenance delays due to runtime errors in the process model [29]. Therefore, it is essential to verify

the workflow model before its deployment. Despite the importance of workflow verification, few commercial workflow systems provide formal verification tools. This lack of verification support can be attributed to the fact that most of the more than 250 commercially available WfMS use a vendor-specific ad-hoc modeling techniques [5] without theoretical framework for the representation, analysis, and manipulation of workflow systems [8]. Although these vendor-provided tools facilitate workflow specification and visualization, and some support simulation of processes under various conditions, they usually do not support formal workflow analyses. While process simulation can provide useful insight into process behavior, it does not address questions about the interrelationships among process components [8]. Consequently, few workflows are thoroughly checked before they are deployed in practice, often resulting in errors that need to be corrected in an ad hoc fashion at prohibitive costs.

There are two research approaches to ensure control flow correctness in workflow models – *build it correctly*, or *check it completely* [31]. The former ([10], [17], structured model in [21]), relying on strict rules in composing the model, may not model certain processes due to syntactical restrictions [21] and may not be very suitable for practical implementation in industry [31]. The latter, like Petri nets ([1], [4], [6], [26], [31], [33]) or the graph-theoretic techniques ([8], [14], [25], [29]), on the contrary, appeals more by allowing the user tremendous flexibility in expressing process requirements offering interesting analysis challenges to the modeler [31]. The Petri-nets-based workflow verification depends on the formalism of Petri nets, which is rarely adopted by existing WfMS, and makes it hard to be embedded into most of WfMS. Therefore, for non-Petri-nets workflow models, it is difficult to apply Petri-nets-based verification techniques as it requires the

transformation from each different modeling paradigm into the Petri nets formalism plus an effort of determining the corresponding structural conflicts in the original model. The majority of business processes have been analyzed using acyclic (i.e. loop-free) free-choice nets, a special class of Petri nets that enjoys the added advantage that *soundness* can be verified in polynomial time [1]. Additionally, establishing soundness in a free-choice net implies that the net is free from deadlock, and is also alive, i.e., no dead tasks [2]. However, the modeling of exceptions or precedence partially destroys the free-choiceness of the equivalent Petri net mapping. Moreover, modeling iteration necessitates the presence of loops in the control flow model, a problem that is yet to be satisfactorily addressed [31].

Graph-based workflow models have been widely used in industry to specify control flows of a business process. Although graphs provide a great flexibility for depicting complex processes in a fairly compact form, their free-form nature also needs to resolve models that may fail due to a lack of support for the modeler to avoid situations that cannot be executed or will behave in a manner not expected by the modeler [12]. Graph reduction ([25], [29]) and block-wise abstraction [14] have been proposed to identify structural conflicts in workflow graphs, but both approaches are limited to acyclic models [3].

This paper presents a novel method of partitioning into a set of acyclic subgraphs and decomposed verification of structural conflicts for a cyclic workflow process, even for nested structures, represented in a directed graph. Our approach of feedback partitioning and decomposed verification is unique and has several distinctive features useful for workflow analysis and design. First, we present two-phased verification of structural conflicts in workflow models. Our method detects certain types of structural conflicts, in the early stage, incurred from the inappropriate composition of feedback flows. And then, our method applies verification to each acyclic subgraph, which is much easier to comprehend and verify individually than the whole workflow model, in general. This decomposition feature has not been seen in any existing workflow verification method. Second, each acyclic flow can be utilized in hierarchically decomposing the given model and is a candidate for a sub-workflow, the knowledge of which is helpful for managing large-scale workflows. Finally, our method is based on a directed graph representation, more generic and adopted widely by the WfMS vendors, and utilizes well-known algorithms of graph-theoretic techniques, which makes it easy to embed our approach into most WfMS.

The rest of the paper is organized as follows. In Section 2, we present the preliminary concepts such as directed graph representation and types of structural conflicts of a workflow model. In Section 3, we present the way of partitioning a cyclic workflow graph into the

subgraphs of acyclic flows with illustrative examples. Section 4 delineates the two-phased verification of structural conflicts and presents the associated theorems. Section 5 discusses related work, summarizes our contributions, and outlines future research directions.

## 2. WORKFLOW MODELS IN DIRECTED GRAPHS

A workflow graph is a directed graph  $G = (N, T)$  with a set of nodes  $N$  and a set of edges  $(i, j) \in T$ , where  $i, j \in N$ . Each edge, called a *transition*, links two nodes and represents the execution order of nodes. A *node* is classified into two types, task and coordinator. A *task*, represented by a rectangle, stands for a unit of work to be done. A *coordinator*, represented by a circle, stands for a point where only one of succeeding paths is selected or several paths are merged. Depending on the types of nodes and the number of incoming and outgoing transitions, nodes can be classified into five categories, i.e., *sequence*, *AND-split*, *AND-join*, *XOR-split*, and *OR-join*, as shown in Fig. 1. *Start* and *End* nodes are used to indicate the beginning and the end of the given workflow process, respectively ([25], [29]).

**Fig. 1.** Classification of nodes in workflow graphs  
Fig. 2(a) illustrates an example cyclic workflow, extending an acyclic example in [29]. We make a simplifying assumption on the workflow graph that a node cannot be a join and split at the same time. Any node that joins and concurrently splits can be converted into a set of a join and a split, separate and connected with a transition.

### Structural conflicts in workflow models

In this paper, we focus on the verification of three types of structural conflicts, deadlock, lack of synchronization, and livelock as illustrated in Fig. 3 ([1], [20], [29]). *Deadlock* refers to a situation in which a workflow instance gets into a stalemate such that no further activity can be executed. This happens when only some partial subset of the join paths to an AND-Join is executed, the AND-Join node  $k$  will wait forever and block the continuation of the process (Fig. 3(a)). *Lack of synchronization* refers to a situation in which the concurrent flows are joined by an OR-Join, resulting in unintentional multiple executions of activities following the node  $k$  (Fig. 3(b)). *Livelock* refers to a situation in which certain loop(s) of tasks are continuously performed, and there is no execution path leading to termination or cannot terminate properly (Fig. 3(c)). Note that livelock occurs only where a cyclic structure exists.

Other types of structural conflicts such as *dangled* nodes are relatively easier to detect than those described above,

from the graph-theoretic viewpoint. A dangled

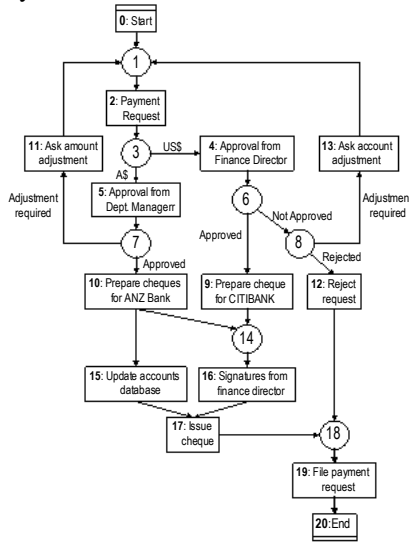

Fig. 2. (a) An example cyclic workflow graph; and (b) the normalized graph

node can be found simply by checking the reachability of each node from the Start node and to the End node.

Fig. 3. Types of structural conflicts

### 3. PARTITIONING A CYCLIC WORKFLOW INTO ACYCLIC FLOWS

Cycles in workflow models are needed for purposes of rework and information feedback. For instance, the workflow in Fig. 2 contains two simple cycles, i.e., a cycle that does not contain any other cycles [19]. Our method identifies and partitions off each acyclic flow from the given cyclic workflow model. At the first iteration of partition, our method partitions off a maximally connected subgraph from the *Start* to the *End*, spanned by all nodes reachable to the *End* without multiple visits to any nodes contained, called *main flow*. If the original workflow model has nested feedback structures, our method proceeds on partitioning further to the remaining subgraph(s) that contain(s) cyclic structures. Otherwise, our method identifies and partition off each additional acyclic *feedback flow* from the remaining subgraph(s). More formal definitions and detailed descriptions of our method are given next.

The algorithm of *Depth-First Search* can be applied to identify the “back edges” where each of those completes a cycle, with the complexity of  $O(|N|+|T|)$  [15]. An edge  $(u, v)$  is classified as a back edge if  $v$  is already discovered but any of its adjacent nodes are not

discovered yet, when to explore edge  $(u, v)$  in the course of *Depth-First Search*. With all *back edges* removed, the rank of each node can be computed from the resulting acyclic workflow graph with the complexity of  $O(|T|)$  [19]. Fig. 2(b) shows the normalized graph of the workflow process in Fig. 2(a), with nodes rearranged by its rank  $r(i)$ ,  $i \in N$ , computed from the resulting acyclic workflow graph and shown to the left in Fig. 2(b). Fig. 4(b) shows another example of normalized graph for a workflow of Fig. 4(a) with nested cycles.

A normalized graph is helpful for identifying feedback structures of a cyclic workflow process. By examining the normalized graphs in Fig. 2(b) and Fig. 4(b), we find some interesting phenomena. First, every dotted upstream transition  $(i, j)$ , with  $r(i) > r(j)$ , merges a feedback flow, which is a back edge as defined above. Second, each dashed transition initiates a new feedback flow. Transition  $(13, 7)$  in Fig. 4(b) has both characteristics. These transitions can be used as the cut sets to group the nodes in  $N$ . Next, we describe an iterative way of identifying those transitions initiating or merging each feedback flow and partitioning the graph of a cyclic workflow into subgraphs of acyclic flows.

#### Steps of a partitioning

The back edges of a cyclic workflow graph found during normalization are called as *Feedback Join Transitions (FJT)*. Each transition  $(i, j)$  of *FJT* has the property of  $r(i) > r(j)$  and corresponds to a distinct simple cycle of a cyclic workflow graph.  $FJT = \{(11, 1), (13, 1)\}$  and  $FJT = \{(11, 7), (13, 7), (23, 19), (24, 1)\}$  for the examples shown in Fig. 2 and 4, respectively. Nodes that merge feedback flows are called as *Feedback Joins*, denoted by *FJ*, where

$$FJ = \{j \mid (i, j) \in FJT\}, \quad (1)$$

$FJ = \{1\}$  and  $FJ = \{1, 7, 19\}$  for the examples shown in Fig. 2 and 4, respectively.

**Definition 1.** For any  $i \in N$ , let the *Order of Feedback* of  $i$ , called by  $OF(i)$ , denote the minimum number of transitions of  $FJT$  to pass to the *End* node. The subset of nodes with  $OF(i) = n$  will be called as  $n^{\text{th}}$ -order *Feedback Nodes* and denoted by  $FN^n$ .

Note that  $N = \cup_n FN^n$ . Nodes of  $FN^0$  do not need any transitions in  $FJT$  to reach the *End* node, and  $FN^0$  can be identified as follows,

$$FN^0 = \{ i \mid R_{FJT}(i, End) = 1 \}, \quad (2)$$

where  $R_{FJT}(i, End)$ , which can be computed with complexity of  $O(|T|)$ , denote the *reachability* of node  $i$  to the *End* node without the transitions of  $FJT$ . That is,  $R_{FJT}(i, End) = 1$  when node  $i$  can reach the *End* node without passing through any transitions in  $FJT$ , or  $R_{FJT}(i, End) = 0$  otherwise.  $R_{FJT}(End, End)$  is defined to be 1. Table 1 shows  $R_{FJT}(i, End)$  for each node  $i$ , resulting  $N - FN^0 = \{ 11, 13 \}$  for the workflow in Fig. 2. It can be shown that  $N - FN^0 = \{ 11, 16, 17, 18, 19, 20, 21, 22, 23, 24 \}$  for the workflow in Fig. 4. The subgraph spanned by  $FN^0$  will be called as the *main flow* and will be denoted as  $MF(Start, End)$ .

**Table 1.**  $R_{FJT}(i, End)$  of each node  $i$  in Figure 2

$i$	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
$R_{FJT}(i)$	1	1	1	1	1	1	1	1	1	1	1	0	1	0	1	1	1	1	1	1	1

**Definition 2.** The  $n^{\text{th}}$ -order *Feedback Joins*, denoted by  $FJ^n$ , is the subset of feedback joins in  $FN^n$ . That is  $FJ^n = FJ \cap FN^n$ . The  $n^{\text{th}}$ -order *Feedback Splits*, denoted by  $FS^n$ , is the subset of nodes that split the subgraph spanned by  $FN^{n+1}$  from the subgraph spanned by  $FN^n$ , identified as  $FS^n = \{ i \mid (i, j) \in T, i \in FN^n, j \in FN^{n+1} \cup FJ^n \}$ .

Note that  $FJ = \cup_n FJ^n$ . By definition 2, we get  $FJ$  as follows,

$$FJ^0 = FJ \cap FN^0. \quad (3)$$

$FJ^0 = \{ 1 \}$  and  $FJ^1 = \{ 1, 7 \}$  for the examples of Fig. 2 and 4, respectively.

The set of nodes in any of  $FS^n$  will be called as *Feedback Splits*, denoted by  $FS$ , where  $FS = \cup_n FS^n$ . Finally,  $FS$  will be identified. Since  $FN^1$  is not available yet and there will be no transition from a node in  $FN^0$  to any node in  $\cup_{n \geq 2} FN^n$ , we identify  $FS^0$  as follows,

$$FS^0 = \{ i \mid (i, j) \in T, i \in FN^0, j \in (N - FN^0) \cup FJ^0 \} \quad (4)$$

$$FS^0 = \{ 7, 8 \} \text{ and } FS^1 = \{ 10, 13, 15 \} \text{ for the workflow in Fig. 2 and 4, respectively.}$$

At each iteration, our method identifies  $FN^n$ ,  $FJ^n$  and  $FS^n$ .  $FN^n$  and  $FJ^n$  is identified by classifying  $N$  and  $FJ$ , respectively. On the other hand,  $FS$  is newly discovered from  $FN^n$ , at each iteration. When all the nodes in  $FJ$  are classified into one of  $FJ^n$ , we can conclude that  $FN^{n+1} = N - \cup_{m \leq n} FN^m$  and no further classification of nodes is required. For instance,  $FJ^1 = FJ$  for the workflow in Fig. 2, and we can conclude with  $FN^1 = N - FN^0 = \{ 11, 13 \}$ . Otherwise, there exist more feedback structures in

the subgraph(s) spanned by  $N - \cup_{m \leq n} FN^m$  and further classification of nodes is required.

### Recursive partition for nested feedback structures

**Definition 3.** For any  $fs \in FS^{n-1}$ , let  $Desc^n(fs)$  denote the set of nodes in  $FN^n$  and  $Desc^{n+1}(fs)$  denote the set of nodes in  $\cup_{m \geq n} FN^m$ , respectively, that can be reached from  $fs$  by the transitions in  $T$ . For any  $fj \in FJ^{n-1}$ , let  $FAncs^n(fj)$  denote the set of nodes in  $FN^n$  and  $FAncs^{n+1}(fj)$  denote the set of nodes in  $\cup_{m \geq n} FN^m$ , respectively, that can reach  $fj$  by the transitions in  $T$ .

**Definition 4.** Let  $fs \in FS^{n-1}$  and  $fj \in FJ^{n-1}$ . The  $n^{\text{th}}$ -order *Feedback Flow*  $FF^n(fs, fj)$  denotes the subgraph spanned by the set of nodes  $\{ fs, fj \} \cup (Desc^n(fs) \cap FAncs^n(fj))$ . The  $(n+1)^{\text{th}}$ -order *Feedback Flow*  $FF^{n+1}(fs, fj)$  denotes the subgraph spanned by the set of nodes  $\{ fs, fj \} \cup (Desc^{n+1}(fs) \cap FAncs^{n+1}(fj))$ .

Note that we can let the main flow  $MF(Start, End)$  equal to  $FF^0(Start, End)$ , assuming that  $Start \in FS^{-1}$  and  $End \in FJ^{-1}$ .

When  $FJ$  is not fully classified yet, there exist at least one  $FF^{n+1}(fs, fj)$  that contains node(s) of  $FJ$ . The corresponding subgraph contains some feedback structures and requires further partitioning. Our method recursively applies the steps of partition to each of these subgraphs. Otherwise,  $FF^{n+1}(fs, fj)$  does not require further partitioning and equals to  $FF^n(fs, fj)$ , by definition.

The workflow of Fig. 2, with  $FN^0$ ,  $FJ^0 = FJ$ ,  $FS^0$ , and  $FN^1$ , can be partitioned into the main flow  $MF(0, 20)$ ,  $FF^1(7, 1)$  spanned by  $\{ 7, 11, 1 \}$ , and  $FF^1(8, 1)$  spanned by  $\{ 8, 13, 1 \}$ , requiring no further partitioning. For the workflow of Fig. 4, we have  $MF(0, 25)$ ,  $FF^1(10, 7)$ ,  $FF^1(13, 7)$ , and  $FF^{n+1}(15, 1)$ . Since  $FF^{n+1}(15, 1)$  contains a node of  $FJ$  not classified yet, i.e., node  $19 \notin FJ^0$ , it contains some cyclic structures and requires further partitioning. In a similar manner, we can get  $FN^1 = \{ 11, 16, 17, 18, 19, 20, 21, 22, 24 \}$ ,  $FJ^1 = \{ 19 \}$ , and  $FS^1 = \{ 2 \}$  from  $FF^{n+1}(15, 1)$ . Since nodes in  $FJ$  are fully classified, we can conclude that  $FN^2 = N - FN^0 - FN^1 = \{ 23 \}$  and derive additional acyclic subgraphs of  $FF^1(15, 1)$  and  $FF^2(22, 19)$ . Table 2 summarizes the results of the analyses for the workflow graphs of Fig. 2 and 4. Note that each finally derived subgraph of a feedback flow, except main flow, matches for distinct simple cycle in the given workflow graph.

(a) A workflow with nested cycles

(b) Normalized graph

**Fig. 4.** Normalization of a workflow graph with nested cycles**Table 2.** Summary of partitioning

Case	Target graph	Classified nodes	Derived subgraphs
Fig. 2	$G(N, T)$	$FJ = \{1\};$ $V-FN^0 = \{11, 13\}, FJ = \{1\}, FS = \{7, 8\}.$	$MF(0, 20)$ $FF^l(7, 1)$ $FF^r(8, 1)$
Fig. 4	$G(N, T)$	$FJ = \{1, 7, 19\};$ $V-FN^0 = \{11, 16, 17, 18, 19, 20, 21, 22, 23, 24\}, FJ = \{1, 7\}, FS = \{10, 13, 15\}.$	$MF(0, 25)$ $FF^l(10, 7)$ $FF^l(13, 7)$ $FF^{l+}(15, 1)$
	$FF^{l+}(15, 1)$	$FN^l = \{11, 16, 17, 18, 19, 20, 21, 22, 24\}, FJ = \{19\}, FS = \{22\}; FN = \{23\}.$	$FF^l(15, 1)$ $FF^2(22, 19)$

The proposed method allows a cyclic workflow model to be analyzed further, if necessary, with several smaller subflows, which are all acyclic. The complexity of this phase can be estimated as follows. Let  $q$  be the maximum degree of feedback and  $r$  be the average number of subgraphs in  $FN^n$  that need to be further partitioned, in the given workflow graph. The identification of  $FN^n$  (with  $FS^{n-1}$  and  $FJ^{n-1}$ ) from  $FF^{n+}(fs, fj)$ , where  $fs \in FS^{n-1}$  and  $fj \in FJ^{n-1}$ , is rather straightforward with  $R_{FJT}(i, fj)$ , where  $i \in FF^{n+}(fs, fj)$ , that has complexity  $O(|T|)$ , where  $|T|$  is the number of transitions in the cyclic subgraph  $FF^{n+}(fs, fj)$ . Therefore, the complexity of this step will be  $O(qr|T|) < O(|N| \cdot |T|)$ .

#### 4. TWO-PHASED VERIFICATION OF CONTROL FLOWS

This section presents two-phased verification of structural conflicts in workflow models. First, it detects certain types of structural conflicts, in the early stage, incurred from the inappropriate composition of feedback flows. And then, it applies verification to each acyclic subgraph, which is much easier to comprehend and verify individually than the whole workflow model, in general.

##### 4.1 Early stage verification on combining partitioned flows

**Lemma 1.** A workflow with an AND- feedback join node  $fj$  will *deadlock* at  $fj$ . A workflow with an AND-feedback split node  $fs$  will potentially result in an *infinite loop* (i.e., *livelock*) or *multiple instances*.

Any  $FF^{n+}(fs, fj)$  split from a XOR-split  $fs$  and merged into a OR-join  $fj$ , which is exclusive with the originating

subflow in  $FN^n$ , will not introduce additional deadlock and lack of synchronization conflict to the combined flow. On the other hand, feedback joins or feedback splits of AND-type incur structural conflicts to the combined flow. Fig. 5 shows that conflicts are caused by combining a feedback flow with AND-controls. An AND-join at  $fj$  can never be started, thus causing a deadlock (Fig. 5(a)). An AND-split at  $fs$  may never end since  $fs$  always triggers a feedback, thus leading to an infinite loop without any type of proper exit from the loop, or may result in multiple instances of subflow  $sf_i$  before the synchronization, if exist, with the subflow  $sf_j$  exited from the loop (Fig. 5(b)).

**Fig. 5.** Conflicts caused by AND-controls as a feedback join or a feedback split

**Lemma 2.** An AND-join  $a-j$  that joins  $FF^n(fs_1, fj)$  and  $FF^n(fs_2, fj)$ , with  $fs_1 \neq fs_2$ , incurs a potential deadlock at  $a-j$  as illustrated in Fig. 6(a). In addition, an AND-split  $a-s$  that splits  $FF(fs, fj_1)$  and  $FF(fs, fj_2)$ , with  $fj_1 \neq fj_2$ , may result in multiple instances of subflow  $sf_j$  or deadlock at  $j$  as illustrated in Fig. 6(b).

In Fig. 6 (a), when there exists some precedence relationship between  $fs_1$  and  $fs_2$ , it is clear that a deadlock conflict will occur at the AND-join node  $a-j$ . The only way to prevent this deadlock is when split  $s$  is of AND-type and both  $fs_1$  and  $fs_2$  always lead to the AND-join  $a-j$  altogether, if any one of them does. But, this cannot be guaranteed and may lead to potential deadlock. In Fig. 6 (b), when there exists some precedence relationship between  $fj_1$  and  $fj_2$ , it is clear that lack of synchronization conflict will occur at one of them visited later. Note that subflow  $sf_1$  or  $sf_2$  may have some XOR-exit, not represented in the figure for simplification, which makes the analysis even more complex. The only way to prevent this lack of synchronization conflict is when the join node  $j$  that subflow  $sf_1$  and  $sf_2$  merge should be of AND-join and both  $sf_1$  and  $sf_2$  should always lead to the AND-join  $j$  altogether, if any one of them does so. But, this cannot be guaranteed either and may lead to potential deadlock. Fig. 6 (c) shows the control-flow-equivalent workflow transformed from the workflow of Fig. 6 (b), by duplicating certain nodes [28] where these additional constraints are satisfied.

**Fig. 6.** Inadequate usages of (a) AND-Join and (b) AND-Split on feedback paths; (c) equivalent control flow transformed from (b) of a special case

Lemmas 1 and 2 can be used to detect certain types of structural conflict related to feedback flows. Our method identifies those ill-structured control flows based on Lemmas 1 or 2 in a workflow model. The decomposed verification phase described next, will assume that the workflow models contain only XOR- feedback split and join nodes.

#### 4.2 Decomposed verification for each acyclic flow

We conjecture that the verification of a given workflow can be done by verifying the *main flow* and each partitioned *feedback flow* of the given workflow, where all of which are acyclic. Theorem 1 below argues the correctness of this approach formally.

**Theorem 1.** *If there exist no structural conflicts in  $MF(Start, End)$  and each  $FF^+(fs, fj)$ , then there exist no structural conflict in the integrated model.*

**Proof:** Any possible additional structural conflicts in the integrated model caused by combining each  $FF^+(fs, fj)$ , originated from and merged into  $MF(Start, End)$ , are of lack of synchronization. After early stage verification with Lemma 1 and 2, each  $FF^+(fs, fj)$  splits from an XOR feedback split  $fs$ , merges at an OR feedback join  $fj$ , and does not cross another feedback flow by an AND-split or an AND-join. Therefore, there is no chance that any additional Lack of Synchronization conflict would be caused in the combined model. The fact that each  $FF^+(fs, fj)$  can be composed in similar manner completes the proof.  $\square$

By Theorem 1, verification of structural conflicts in a cyclic workflow model can be done by verifying structural conflicts of  $MF(Start, End)$  and each  $FF^+(fs, fj)$ , which are all acyclic. That is, in decomposed verification approach, we only need to verify *acyclic* flows. This is a very important feature of our approach and can lead to simplified verification and significant computational efficiency compared to those approaches that verify a cyclic graph as a whole. For instance, the graph reduction technique [25] can be applied to a cyclic workflow graph after the original graph is partitioned into  $s$  subflow graphs. As a result of partitioning, the computation effort can be even improved from

$O((|N|+|T|)^2 \cdot |N|^2)$  ([3], [25]) to  $O((|N|+|T|)^2 \cdot |N|^2 / s^3)$  by dividing  $|N|$  and  $|T|$  by  $s$ , respectively.

#### 5. CONCLUDING REMARKS

Workflow analysis and design is a fundamental task in business process management because of the recent surge of e-business process automation efforts in the corporations worldwide. Although hierarchical decomposition of a complex workflow process is an useful step in workflow analysis and design, until now there has been no reported work of its automated support in the literature. When the process model is complex, it is quite perplexing for a human to recognize substructures of potential subprocesses [2].

In this paper, we proposed a unified approach of feedback partition and decomposed verification of structural conflicts that can handle cyclic workflows efficiently. We showed how to identify the main flow and each feedback flow that completes each simple cycle, which are all acyclic. Hierarchical decomposition of a workflow model by feedback structures can make workflow analysis and design more accurate and efficient and can lead to a better design. We also showed that verification of structural conflicts in a cyclic workflow model could be done by independently verifying structural conflicts in main flow and each feedback flow, which are all acyclic. That is, in decomposed verification approach, we only need to verify *acyclic* flows.

Our work is related to three main studies in workflow verification, namely the graph reduction approach ([25], [29]), the Petri nets approach ([1], [4], [6], [33]), and the logic-based approach ([11], [27]). The graph reduction approach detects structural errors by trying to reduce the original workflow graph into an empty one. If this attempt fails, the workflow is determined to contain errors. One main drawback is that the graph reduction technique cannot handle cyclic workflows and overlapping patterns algorithmically. The Petri-nets-based workflow verification depends on the formalism of Petri nets. Therefore, for non-Petri-nets workflow models, it is difficult to apply their verification technique. The logic-based approach depends on the expressive power of propositional logic and does not take advantage of instance flows in its verification method. Furthermore, none of these approaches use the concept of feedback partitioning, which has been shown to provide advantageous features in workflow analysis and design. Our work unifies process decomposition and verification while other verification techniques focus mainly on process verification. In sum, our approach provides a useful, if not better, alternative to existing workflow verification methods.

The issues that merit future research are: to establish results for verifying correctness of a workflow model including other perspectives, for instance the data-flow;

transformation of a free-form graph-structured workflow model into a structured model, like in BPEL4WS [10]; to extend results for further workflow analysis of process reengineering.

### ABSTRACT

This paper presents a model for designing the pricing policies for the supply chain whose channel is integrated with retail and e-tail. In order to incentive the retailer, the manufacture in the supply chain adopts return policy promising that any unsold product can be returned to the manufacture for a partial refund in the end of the selling season. How can the manufacture coordinate the pricing policy between the retail and e-tail channel and what is the optimal pricing policy for the wholesale price and return policy which will make the supply chain's profit maximize are the central issue in the supply chain coordination. Pricing policies between retail and e-tail are researched under the Stackelberg price competition model firstly. Under the optimal competing pricing policies model, we further obtain the equilibrium pricing for the wholesale and return price that make the supply chain maximize through the expected profit analysis. Then further research dimensions are discussed in the end of the paper.

**Keywords:** pricing policy, supply chain, profit, electronic commerce

### 1. INTRODUCTION

In the past decade, rapid developments in information and telecommunication technology have substantially changed the landscape of organizational computing. Electronic commerce (E-commerce), including Web-based commerce, mobile commerce (M-commerce) and ubiquitous commerce (U-commerce), is based not only on developments pertaining to the Internet compound, but also on prior technological and organizational innovations arising from the combination of telecommunications and organizational computing[1]. As the most rapidly developing, e-commerce via the Internet (i.e., Web-based commerce) has substantially affected the business world since the commercialization of the internet and evolution of the dot.com in the early 1990' and it is commonly believe that the transactions volume via e-commerce will continue to grow in the coming years[2]. Different companies have different uses of the e-marketplace and different e-marketplaces take different roles. There is an increasingly number of company which takes e-marketplace as a distribution way which named as e-tail. By this way, many companies, such as dangdang.com in china, seems to make success possible. However, in most case, it turn out that the most workable solution is the way that is integrated with e-tail channel and traditional retail ones. By this hybrid channel, customer can have more than one way to purchase commodity by their attitude or convenience.

With the development of e-commerce, e-tail become as a crucial retail way in distribution channel more and more in practice and there is an increasingly number of research paper that is focus on the distribution channel which is integrated with e-tail and retail. For example, Dong-Qing and John J study the equilibrium pricing policy under the e-commerce [3]. Tsen-Ming Cha studied the return policy in supply which is integrated

with e-marketplace [4]; Chen and Siems discusses the relationship between the B2B e-marketplace announcements and the shareholders response in the financial market [5]; Chiang studied the dual channel supply chain design for goods that do not provide a large service (value) such as books, CDs, etc. their results show the manufacturer can mitigate the profit loss by adding a direct channel [6]. Besides these researches, Iyer examined how manufacturers should coordinate distribution channels when two retailers compete under price and non-price attributes in supply chain earlier [7].

This paper focuses on providing an analytical pricing model for using both e-marketplace and retail as distribution channels in a supply chain instead of proposing a conceptual framework. We study a supply chain which is integrated by a return policy and the manufacture can distribute products by directly "on-line" (by e-Marketplace, referred to as e-tail) and traditional channel by which the manufacture wholesale the products to the retailer. Although, the mix of distribution with e-Marketplace has added a new dimension of competition to the firm's distribution channels, the manufacture faced with the problem how to design the pricing policy in the e-tail and regular retail channels in order to coordinate the distribution channels. Also the manufacture must decide the wholesales price and the returned price before the selling season in order to maximize mutual profit for manufacture and retailer. In fact, the analysis of return policy for channel coordination has been studied by Pasternack in the paper Optimal pricing and returns policies for perishable commodities which published in the marketing science literature in 1985 [8]. However, Pasternack's study didn't consider the impact of e-commerce on the commodities distribution because there is no e-commerce experience in that time. Cha study the optimal return policy under two undisturbed market [4]. Also, Hon-Shiang Lau studies the manufacture's pricing

policy strategy and return policy for a single-period commodities in which the retail channel didn't integrate with e-marketplace [9]. However, with the emergency of e-commerce, more and more manufacture integrates e-marketplace as the aid way to distribute their products [10], such as some in china. And the manufacture in supply chain is faced with the new problem how to coordinate the pricing policy among different distribution channels.

In this paper, we assume a two-echelon supply chain with a single manufacturer who supplies a single item to the retailer and the manufacture adopts both e-tail and regular retail channels to distribute products. Both the channels are designed for different customers respectively and the customer can acquire value-added service by regular retail channel which cannot receive from the e-tail channel; however, the price attached to e-tail would be lower. Under different types of retail channels and service level, what are the equilibrium pricing policies that manufacture should adopt for the e-tail and retail channels in order to coordinate the sales quantity and the profit in different channels? We will examine the pricing equilibriums between the e-tail channel and retail channel under the types of competitive pricing schemes: Stackelberg competition models. Under the Stackelberg model, the manufacture, as the leader of the market, announce the e-tail price before the selling season firstly. Also, the manufacture has considered the retailer's reaction prior to announce the e-tail price. As the follower in the market, the retailer reacts to the e-tail price by choosing retail price and the corresponding service level to maximize its own selling quantities and the profit.

As a result, we obtain the equilibrium prices between e-tail and retail channels. Because of promising in contracts, the retailer can return any unsold products to the manufacture for a partial re-fund products after the selling seasons which can incentive the retailer to order more quantities products and work harder for retailing, by this way, the manufacture shares the risk caused by demand uncertainly with the retailer by this way. Also, the retailer can acquire reasonable profit by different order quantity and the retail price. After we study the competing pricing policy between the e-tail and retail channels under the Stackelberg competing model before the selling season, the equilibrium pricing policy for wholesale price and return price is studied in the paper which can coordinate the profit and risk between the manufacture and retailer.

On the basis of the discussion, the paper is organized as follows: the quantity model that the supply chain is integrated with retail and e-tail channel is set up in section 2, and the Stackelberg competing pricing model is presented in successions; as a result, we obtain optimal pricing policy pertain to e-tail and retail channels under the discussion on the model. Furthermore, we derive the expected profits for all the parties in the supply chain

under the wholesales price and returns policy in section2. After deducing, the optimal pricing policy for the wholesale price and returns policy is proposed in the same section. In the end, concluding remarks are presented.

## 2. MODEL

Based on the above discussion, we consider a supply chain inside which a single-product manufacturer-retailer system mixed with an e-tail distribution channel in addition to a regular retail channel where the manufacture sells the product to a retailer at a fixed market with a unit wholesale price of  $w_0$  and the unit production cost at the manufacture is  $c$ . The retailer then sells the product to the customers in the lower echelon with price  $p_2$ . In the past, the manufacture can only distribute items by this way. However, with the development of e-commerce, the manufacture can select an e-tail channel to sell the products directly on-line at the same time in which the price is  $p_1$ . At the same time, the retailer competes against the on-line selling by adding value service via the traditional channel when distribute the product to lower echelon at a retail price  $p_2$ . The cost which is produced by value-added service defined as  $c(y)$ , such as speciously packing for books and CDs or properly maintain service for cars which are needed for some customers who are assumed to be heterogeneous and are able to purchase a product either from a retail channel or directly from an e-tail channel and some of the them would like to purchase directly from the manufacturer at a lower cost, while others are willing to pay more for the value added by the retailer that are unavailable in e-tail, on the contrary. Because of the value-added service, the retail price  $p_2$  is typically expected to be higher than e-tail price  $p_1$ .

After the selling season the retailer can return any unsold products to the manufacture under the returns policy on the price  $w_1$  which is promised in the contracts, so the manufacture shares the risk caused by demand uncertainly with the retailer by this way. As we discussed above, the retailer can acquire reasonable profit by different order quantity and the retail price  $p_2$  either. In this paper, we assumed that the manufacture can sell any returned products by the e-marketplace faced with global and local markets and whose demand is assumed to be immensity. In the past, without the e-commerce, the manufacture would salvage the returned products at a price  $\mu$  that more lower than  $p_1$ . However, any unsold products cost the retailer a unit holding cost  $h$ . In the past, there is an example of using both e-tail and traditional retail in china, such as eguo.com.

In this paper, we assume all information is common to both parties which mean that the retailer has complete information about manufacture (such as unit production

cost, etc) and vice versa. With the above details, Fig 1 shows the structure of the supply chain with the use of the e-tail.

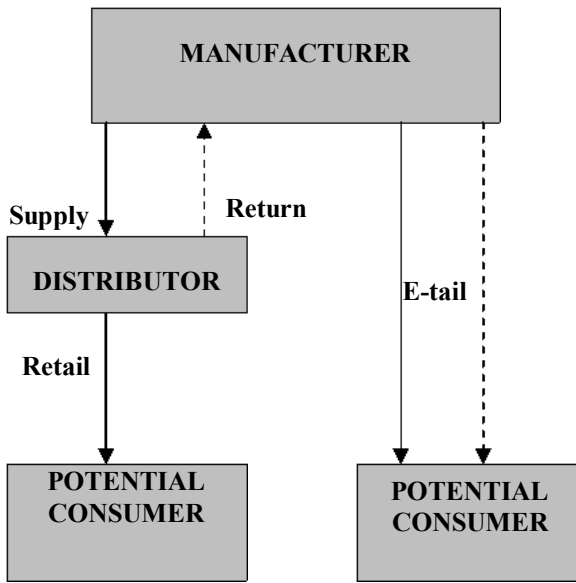

Fig.1. a supply chain mixed with e-tail and retail

Firstly, we have the following notation

$\pi_1$  Profit of the manufacture;

$\pi_2$  Profit of the retailer;

$\pi$  Profit of the supply chain;

$d_1$  Demand via e-tail channel;

$d_2$  Demand via retail channel;

$p_1$  Unite price of the e-tail channel;

$p_2$  Unite price of the retail channel;

$w_0$  Unite wholesale price of the product;

$w_1$  Unite return price for the unsold product

$v$  Cost of unit value-added service

$q$  Quantity of product retail ordered from manufacture;

Under the Stackelberg model, the manufacture, as the market leader, firstly announced the unit e-tail price  $p_1$  to maximize payoff  $\pi_1$  on consideration the expect reaction price before the selling season; as the follower of the market, the retailer then reacts to the manufacture's price policy  $p_1$  by adopting unit price  $p_2$  and value-added service which unite cost is  $v$  to maximize its market share and own profit  $\pi_2$ .

So we can define the profit for manufacture, retailer and the supply chain as following:

$$\pi_1(p_1, p_2) = p_1 D_1(p_1, p_2, v) + w_1 D_2(p_1, p_2, v) \quad (1)$$

$$\pi_2(p_1, p_2) = p_2 D_2(p_1, p_2, v) - w_0 D_2(p_1, p_2, v) \quad (2)$$

$$\pi(p_1, p_2) = \pi_1 + \pi_2$$

$$= p_1 D_1(p_1, p_2, v) + (p_2 - c(v)) D_2(p_1, p_2, v) \quad (3)$$

We define the e-tail channel demands  $d_1$  and retail demands  $d_2$  as following which are similar to that in Tsay et al [11] and Choi [12]:

$$d_1 = D_1(p_1, p_2, v) = a_1 - b p_1 + \lambda(p_2 - v - p_1) \quad (4)$$

$$d_2 = D_2(p_1, p_2, v) = a_2 - b p_2 + \lambda(p_1 + v - p_2) \quad (5)$$

Where  $a_i$  is the market base through channel  $i$  ( $i = 1$  for e-tail and  $i = 2$  for retail),  $b_i$  represents the marginal channel demand per respective channel price, and  $v$  measures the marginal retail demand per retail service value added. The parameter  $\lambda$ , termed discussion intensity, is adopted to describe the shift between the two channels with regards to the price and value.

We assume that before the selling seasons both the retail and the manufacture expect that the entire product  $q$  will be sold by either e-tail or retail, which will make their profit be maximized. Under this consideration, we can formulate the Stackelberg pricing equilibrium of  $p_1$  and  $p_2$ . In the competing pricing model, we assumed that after the manufacture announced the e-tail price  $p_1$  the best-reaction price that the retailer would adopt to maximize its profit is  $p_2$  which make the following equation satisfy:

$$p_2(p_1) = \arg \max_{p_2} \pi_2(p_1, p_2) \quad (6)$$

Anticipating against price  $p_2$  that would be adopted by the retailer, the manufacture will select the best e-tail price  $p_1$ , which is given as:

$$\max_{p_1} \pi_1(p_1, p_2(p_1)) = p_1 d_1 + w_1 d_2 \quad (7)$$

Taking the derivative of (3) with respect to  $p_1$  and let  $\partial \pi / \partial p_1 = 0$  yields:

$$p_1 = \frac{2a_1b + 2a_1\lambda + a_2\lambda + v\lambda + c(v)b\lambda}{4(b+\lambda)^2 - 2\lambda^2} + \frac{c(v)\lambda^2 + 2wb\lambda + 2w\lambda^2 - v\lambda^2 - wvb\lambda}{4(b+\lambda)^2 - 2\lambda^2} \quad (8)$$

As the same way, we can obtain:

$$p_2 = \frac{\lambda p_1 + a_2 + (\lambda v + c(v) + w)(b + \lambda)}{2(b + \lambda)} \quad (9)$$

$p_1$  And  $p_2$  is the competing equilibrium price that the manufacture and retailer decide by Stackelberg model before the selling seasons, which would make their profit maximize. Under the equilibrium pricing policy, they will contract the wholesale price  $w_0$  and return price  $w_1$  in order to share profit and risk in the cooperation process, So we define the  $\pi_1, \pi_2, \pi$  as the real profit

for manufacture, retail and supply chain end the selling season. Then we discuss the optimal wholesale price  $w_0$  and return price  $w_1$  in the following.

End the selling season, profit for the manufacture, retailer and supply chain are defined as following:

$$\pi_r = (p_2 - c)q - (p_2 + h + c)(q - L) \quad (10)$$

$$\pi_{r2} = (p_2 - w_0)q - (p_2 + h + c)(q - L) - w_1L \quad (11)$$

$$\pi_r = \pi_r + \pi_{r2} = (p_2 - c)q - (p_2 + h + c)(q - L) - w_1L \quad (12)$$

Where  $L$  shown the amount of returned items after the retail selling season and it is defined as:

$$L = \max(0, q - x) \quad (13)$$

From the equation (10), (11) and (12), we can formulate the expected profit for the manufacture, retailer and supply chain as:

$$E[\pi_r] = (p_2 - c)q - (p_2 + h + c)(q - E[L]) \quad (14)$$

$$E[\pi_{r2}] = (p_2 - w_0)q - (p_2 + h + c)(q - E[L]) - w_1E[L] \quad (15)$$

$$E[\pi_r] = (p_2 - c)q - (p_2 + h + c)(q - E[L]) - w_1E[L] \quad (16)$$

The expected returned products shown as following:

$$E[L] = \int_0^q (q - x)f(x) dx \quad (17)$$

Taking the derivative of (15) (16) with respect to  $q$ , we can show the result of the optimal product quantities for retailer and supply chain as:

$$\frac{dE[\pi_{r2}]}{dq} = (p_2 - w_0) - (p_2 + h + c)(1 - F(q)) - w_1F(q) \quad (18)$$

$$\frac{dE[\pi_r]}{dq} = (p_2 - c) - (p_2 + h + c)(1 - F(q)) - w_1F(q) \quad (19)$$

Let (18) (19) equal to zero, we can acquire the optimal product quantities respectively for retailer and supply chain. It is obviously that there is only one solution for the optimal quantities in the supply chain. So we can obtain equation (20) from equation (18) (19) which are shown as:

$$\begin{aligned} & \left( \frac{p_2 - c}{p_2 + h + c(1 - F(q)) - p_1} \right) w_1 - w_0 \\ & = \left( (p_2 + h) \left( \frac{p_2 - c}{p_2 + h + c(1 - F(q)) - p_1} \right) - p_2 \right) \end{aligned} \quad (20)$$

The manufacture and the retailer have decided price  $p_1$  and  $p_2$  before the selling season, which we have explained by Stackelberg competing model shown in (8) and (9). From the equation (20), we can find that the wholesale price  $w_0$  and return price  $w_1$  are the variable which can the manufacture use as the way to share the profit and risk with retailer by different wholesale price  $w_0$  and return price  $w_1$ . In order to make the profit of the supply chain maximize, price  $w_0$  and  $w_1$  must satisfy the equation (20).

### 3. CONCLUSION

This paper shows how a monopolistic manufacture of a single-period commodity could establish his pricing policies in a mixed e-tail and retail distribution channel in the supply chain under the e-commerce environment, in which the manufacture and retailer consider not only the wholesale price and return price, but also the competitive equilibrium pricing policy between the e-tail and retail firstly which we demonstrate by Stackelberg competition model. Also we obtained dynamic equilibrium equation between the optimal wholesale price and return price, which can make the supply chain's profit maximize and serve as a way for the manufacture and the retailer sharing the profit and the market risk.

In order to simplify, we assumed that all returned product would be sold entirely by e-marketplace in this paper. However, as an extension, we can research the condition in which the returned products are still left in the e-tail in the end, which will make the research more complex. Also, we can also discuss the manufacture and the retailer announces the price simultaneity, so the price equilibrium can not be received by Stackelberg competition model. In more generally, we may further study equilibrium prices for different demand forms contrary to the linear demand which is assumed in this paper. Further study could be done how the incentive plan can be set to coordinate the manufacture and the retailer to make more contribution to the supply chain.

## ABSTRACT

Drawing lessons from the development of cities at home and abroad success and lost experience, through practice research, this paper systemically analysis the evolution of urban economy space. In the scope of global industrial supply chain's recomposing, it is discusses that modern city's function structure characteristic, focusing "integrative logistics management service". According to Dalian's geography and resource advantage in district industry supply chain, this paper also proposes the digital CBD planning of Dalian which focuses integrative logistics management service.

**Keywords:** industrial supply chain, recomposing, integrative logistics service, digital CBD

## 1. EVOLUTION OF URBAN ECONOMY SPACE AND RECOMPOSING OF INDUSTRIAL SUPPLY CHAIN

The city is a zone that has high population density and depends on the second and third industries. And as the center of around area, it performs advanced social, economic, and cultural activities and has many organizations that benefit from complicated aims. Thus the city plays important roles in the development of district economy: district manufacture center, district currency center, district service management center, district human resource center, district intercommunion center, and district innovation center<sup>(1)</sup>.

It is proved through investigation that the forming and development of city lies on four factors: relative benefit, intramural scale economy, traffic cost and convergence economy. With the change of ages and the development of society, those factors have different weights, which determines the forming, flourishing and declining of the city.

As the theory of evolution of urban space, the forming and development of modern city basically follows the "equation- convergence- separation-new and advanced equation" evolution course. Because of scale economy and scope economy, the space convergence of some leading industries is higher (the trade cost is lower) in certain districts (cities), which makes many industries concentrate in certain kernel enterprises/industries, and forms the convergence effect of urban space. At the same time, with the increasing of convergence scale, the scarcity of recourses (soil and so on) makes the opportunity cost increase and the diseconomy phenomenon appear, and the advancement of technology makes the structure of scope economy change greatly. In the dynamic "convergence-separation" process of urban development, the scale of city is increasing, and population flow accordingly direct contact<sup>(2)</sup>.

In the analysis of industry system, Dicken's supply

chain theory is more representative. He think that in the producing process of certain manufacture or service, supply chain is the combination of a series of increasing value and interactive and interrelated basic activities, consisting of gathering of raw and processed materials, transportation, storage, gradual process, assembling and distribution of manufacture and service and other functions. In supply chain, every activity relates each other through different technology devotion and traffic and communication, enclosing the economic system that can supply essential management fund. And moreover, all activities should been adjusted, standardized, and controlled<sup>(3)</sup>. The industrial creating value process is represented by the value chain that is same to supply chain.

In the traditional economy increasing theory, the economy increasing mainly dues to the actual elements such as capital, soil, labor and so on, and namely the basic activities of supply chain. After 1960s, western nations' economical increasing have obviously changed, in which the status of traditional manufacturing descended, on the other hand, information industry that was represented by finance and information management, rapidly developed, and more and more accelerated the development of GDP. Information industry became the important factor of the development; service economy (producer services) gradually replaced industry economy; besides the basic activities of supply chain structure, elements took more and more weight in industrial increment. Having undergone the phases of resource denseness, labor denseness and capital and technology denseness, western industrialized countries have been the phase of technology and intelligence which is called as "knowledge-based economy" and in which not only science and technology, though the "accumulation-overflow", but also the devotion of capital, labor and other essentials can gain increasing income, so can the hole economy system<sup>(4)</sup>.

Firstly, this industrial variety (upgrade) represented as the alter of industrial innovation mode, that is to say,

innovation was the continuous and linear process of invention, examination, manufacture and distribution, but now it change the discontinuous and nonlinear process. In the studying economy and soft industry system that the most important resource is knowledge, the innovation always exists in the manufacture process, “studying in practice”. Given as an example, the “modularization” manufacture based on decentralization and centralization and recomposing knowledge just is an innovation of the manufacture mode and the consumption mode<sup>(5)</sup>.

According as the space benefit and the accessibility that are gained by the manufacturing space benefit and cost, we can separate the space structure into three types: central cluster, decentralized cluster and random spread. It has been proved that whichever type of recomposing supply chain has the “direct separation-pervasion-second convergence” characteristics<sup>(6)</sup>:

Firstly, the supply chain changed from the lengthwise unification that takes products as core and enterprises as cell to the supply chain one that takes cooperating management as core and relative industries as cell, and the logistics was separated from the manufacture and distribution<sup>(7)</sup>.

Secondly, considering that the urban center has higher rent and more expensive accessibility, only the factors of the supply chain that have the highest boundary benefit can be gathered. But the urban center district has the advantages in cooperation management, public service, information communion, sharing knowledge, and manpower resource, so industries always locate management center and distribution center on this district.

Thirdly, according to the cost counting, with the descending of rent, the manufacture center of industries diffuses from urban center district to qui-center district. Generally, core enterprise locates its manufacture base on the urban qui-center district and the accessional enterprise encloses the core one.

Fourthly, the substance of soft manufacture is “Just-In-Time (JIT)” mode, which demands that the reaction between producer and consumers is in time, and thus the logistics activities must focus on the manufacture and distribution. The development of traffic technologies makes the transportation cost generally lower and the increasing of urban rent makes the storage cost more and more higher. Accordingly, physical distribution closes up the manufacture center and distribution center, services the manufacture and distribution of goods, and the logistics center or the distribution center is located around or near the urban center.

Fifthly, the final aim of recomposing supply chain is to apply the “integer supply chain—through specialized

dividing work, achieving the increasing of scale benefit”, which is represented by the cooperation management of supply chain elements, what is called “cooperation manufacture”<sup>(8)</sup>. In the steps of supply chain, the logistics needs more information and higher supply level of the public property, so information management and cooperation activities give the shape of the center of logistics service center, which mostly is located at urban center districts.

## 2. SPACE CHARACTERISTICS AND FUNCTIONS OF MODERN URBAN CBD

The modern urban CBD (Central Business District), generally is the urban center district. It refers to the most convenient joint, and commonly is recognized by people, and is relatively certain.

With the development of technology and the advancement of global economy, CBD has more and more been the center of complicated economy activities and the support of economy increasing, in big cities and even bigger districts. Because of the standing “convergence- separation” action, supply chain’s elements lie on the top of the value chain, mostly concentrate in CBD. So the situation affects exclusive economic effect, communion effect, and space effect, which enhances the convergence and takes bigger appeal. Therefore, the urban CBD is not only the symbol of glory and development, but also the support of extending influence. As an urban space modality, CBD has following characteristics:

Firstly, the district economy center. Geographically, CBD is generally on the center of a city, and economically, it is the most convenient spot. The frequency of communion that CBD provides determines its role in the city and more abroad zone.

Secondly, the third industries intensity. The third industries are gathered at CBD, and the relative enterprises are dense. Generally, the intensity index of the third industries at the CBD is hardly lower to II, that is to say, the whole area of the third industries is more than 40% of the CBD’s area.

Thirdly, high convenience and strong crowding. The outer and inner traffic of CBD is three-dimensional, and the traffic area is commonly 20% of the whole area. CBD has the most developed inner and outer traffic, and can form a convenient traffic net. Which offer people the good opportunity to pass. Relatively, the crowing degree is the highest in the city.

Fourthly, using of the space is developing vertically, and has high modern and intelligence level. Most buildings are high and even super-high. Using the advanced structural material, equipment, and communication products, the constructions of CBD is intelligent, so they can satisfy the require of modern official business.

Fifthly, rent is expensive. The area of CBD is scarce and the house cost is expensive.

Recomposing supply chain results in the change of industrial elements' structure. Accordingly, the space layout and the function of cities has altered<sup>[9]</sup>.

Firstly, manufacturing spreads to the urban qui-center district. Before the middle phase of industrialization, most office buildings, storages, factories, and shops are lied at CBD. But in the last industrialization ages, most manufacturers begin to move to the qui-center districts of the city.

Secondly, the unmanned trend. That mainly refers to the population density of urban center is lower and lower, and the house area is reducing.

Thirdly, the advanced development of the service industry. Service economy weights more in the value chain. The advantage of the CBD in service industry makes it competitive in the service industry and it can function the big scope and scale management of supply chain.

Fourthly, the structure of the material services adjusts. The type, service object, scale and quality of the material services at CBD have great changes. The internationalization and intelligent are current. The business hotels are the main force of restraints and traditional hotels, and super-markets are abundant.

Fifthly, commonality goods' importance is obvious. Because the CBD functions the economy cooperation and management, social economy security is more and more important. The government, tipstaff, chamber of commerce, and other functional departments have higher efficiency than those in other districts.

Those changes directly result in the reorientation of urban CBD. Because the core of industry benefit has transferred from physical elements to intelligent elements, from manufacture to management, the functions of urban CBD are restricted by the "cost-benefit" curve, and transfer from the manufacture center to the management center.

The industrial increment generally consists of four parts: value in shape, value on time, value in space, and value on possess. It is obvious that the industry management center and distribution center base the "integration of supply chain" theory. According to modern logistics conception, the logistics is a industrial system; is the integration and optimization of transport, storage, loading and unloading, conveying, packing, current processing, distribution, information disposing and other elements. Society economy activity is an integration of material distribution, information current, manpower resource, and capital. From the scope, the economic function of urban CBD is represented by

management of information, manpower resource and economic services.

### 3. ANALYSIS OF THE EVOLUTION OF DALIAN'S CBD

Such as the former depiction, most western cities takes CBD as the general management, distribution, and service center, which many business, economy, office activities. According to foreign CBD, our native urban CBD has developed through different path. Native CBD developed on the base of traditional center district. Traditionally, the center of a city usually is the geometrical center or the axes of the urban area. In the latter-days, with the invading of western capitalism and the slow development of national economy, the rudiment of CBD appeared in the seashore cities. At the same time, the retail commerce took shape in traditional commerce and handicraft industry areas. In the planned economy ages, the structural elements and layout of urban CBD had obvious changes, and effected by Soviet model, CBD's function is the center of administration management and public campaign. Since the Reform, the inner impetus of market economy promoted our native city internationalization development<sup>[10]</sup>. But the general service function is still lack. The reasons are following:

Firstly, the reconstructing of old city zone mostly is physical reform and compensation. It can hardly aim to renew and develop the city function, and cannot practice multi-objective, multi-factor and multi-approach reform. Secondly, the imbalance of our native industries development behaves as the lag of the construction of public physical and economic services. With the rapid development of native economy and the distinctness of that China becomes the manufacture center of the world, Chinese economy development has involved in the global situation<sup>[11]</sup>. It has been proved by investigation that our nation can not afford the demand of recomposing supply chain in the logistics management services<sup>[12]</sup>.

Thirdly, the low density of CBD became the inanition. The development of urban service function is slower than the demand of society economy developing, so manufacturing move out of the CBD, at the same time, the supply of service industry is not enough. And the government's compulsive policy make it worse. Fourthly, the bad circle of physical market of CBD formed. The lag of general services makes the layout and constructing of many public business buildings straggled.

The history of Dalian city is relatively short, and the programming and constructing not only has seashore structure characteristic, but also has been influenced by the colonial age when Dalian was colonized by Russia and Japan. After almost one hundred years constructing, a CBD distribution has formed in Dalian that centers on

the “Qinniwa bridge-Zhongshan square-Bay square” triangular district. Since 1990, with the rebuilding of old city zone, enclosing the former CBD and aiming at achieving the international level, Dalian government has weightily programmed and constructed a 2.8 sq.km. area from Bay square to Civil aviation mansion. And obviously a functional distribution has basically formed, which emporiums, office buildings and hotels .

In general, the layout and functional characteristics of Dalian CDB, is same to the problems of other cities. But Dalian CDB has its characteristics:

Firstly, the competition of retail trade is too serious. Many big bazaars have higher sale but lower benefit. The situation is worse in the super-markets such as Wal-Mart.

Secondly, the restaurants hardly analysis the clients. Service has no otherness and the service level is relatively lower.

Thirdly, the competition of general services is too weak. The scale economy and scope economy cannot form. It is difficult that achieving higher services to supply the demand of clients. Those are the reasons why many office buildings leave unused.

Fourthly, the lag of public physical services is serious. Because the local benefits bring the public resources waste and the trade charge is too high, the public resources cannot be shared.

Modern economy is the typical “seashore” economy, and the port is the hinge and core of an economic chain. With the global development of the world economy, markets have managed elements and not managed products. The development of nations more and more lies in the outer trade and international exchange. This trend directly accelerates the “tertiary port” forming. This sort of port combines the advantages of container transport, multi-type transport, international trade, general logistics management.

The “tertiary port” not only should have traditional services, such as loading and unloading goods, distribution of information, providing services for the clients, but also should supply many modern services:

Firstly, providing industrial services.

Secondly, providing distribution services.

Thirdly, providing general logistics services of supply chain.

In the above services, the last one is the most important, whose level directly influences the using of port<sup>[3]</sup>. Port industry is one of the important industries of logistics. The “tertiary port” has been the core element of modern logistics, which takes the global supply chain management as aim and emphasizes on the general logistics management.

As the estimate of World Bank, the last year, the logistics cost of China National Economy is 1,600 billion RMB, and the logistics of China has been shaped. According to the statistics, in 2001, the total amount of commodity is 3,760 billion RMB in China, that of yield material is 5,500 billion RMB, and that of imports and exports is 500 billion dollars. The bigger overseas demand provides wide marketable space.

As the hinge port of northeast Asia, Dalian is one of the important cities that are taken as national logistics basic constructions, and Dalian takes the domain role in the district industry supply chain. The advantage of Dalian is just its ports, likes Singapore and Hong Kong. So the development of Dalian city lies on the interplay of port economy and city function<sup>[4]</sup>.

As one leading industry, the general services industry should aim at the “port economy”. Recent years, the depression of many hotels and office buildings that are primary elements of general services industry can prove this point.

After China entered WTO, with the flourish of native and international trade and the gradual opening of native market, Dalian logistics industry has advanced opportunity and great potential. Dalian has taken logistics as support industry and put forward the stratagem that constructing Dalian port as international ship center<sup>[5]</sup>.

But in the layout and programming of district logistics, mainly emphasizing on “hard” devotion, and less considering the “soft” devotion, which may waste much capital and substance. The development of Dalian logistics should take the district advantage as bases, and take the demand of global industry supply chain as criterion. This logistics system has following characteristics:

- ò Space: shorter traffic distance and better traffic conditions
- ò Time: shortcut and efficiency
- ò Circumstances: comprehensive living and business establishments and grace sights
- ò Commerce: comprehensive administration and information services, reducing cost and increasing efficiency

Not only from district resources advantage and the demand of marketing circumstances, but also perfecting the competition and driving the whole district economy, it is necessitous that constructing the comprehensive logistics services stage to strengthen Dalian CBD’s functions.

It is obvious that at present, rare services are the effective supply, regulation and conformity following functions:

Firstly, public physical services

Secondly, comprehensive society logistics management

services

Thirdly, logistics clients, physical logistics recourses

#### 4. CONCLUSIONS AND SIGNIFICATION OF RESEARCH

Constructing digital CBD, can strengthen the services functions of comprehensive logistics management of Dalian, and absolutely combine the district advantage and resource advantage of Dalian. So Dalian urban CBD's functions can rapidly adapt the press of global economic, and the CBD becomes the competitive center of city or the area and accelerates the recomposing of district industry supply chain.

### ABSTRACT

Due to that many fuzzy and uncertain association relations represented by some phenomenon in the process of enterprises cooperation in supply chain, data mining method was try out in this paper. At first, concept and deducing procedure was introduced, and then 300 samples from a survey was pretreatment, in succession cooperation relations of enterprises in supply chain was studied combined with association analysis method. Some acceptable conclusions were obtained, which can explain the relations between modality and measures of cooperation of enterprises reasonably.

**Keywords:** Association rule, Supply chain, Partnership

### 1. INTRODUCTION

Supply chain is a whole function net model that connects from supplier, manufacturer, distributor, retailer and the consumer. Purchase the material, manufacture the work-in-process and end product, and then transfer the product to the consumer by the distributed net, with the controlling flow of information, logistic and finance and surrounding the core enterprise [1]. Nearly every enterprise exists and develops in the supply chain. Many scholars, enterprisers and the consulers are researching the supply chain partnership. In this paper, we focus on the enterprise in Chinese Tianjin and sample of 300 enterprises. We studied the partnership from supplier and client at two aspects, one is how they exchange information and the other is how they solve the trade dispute. For the one aspect, we research the relationship of the cooperation range and time between information exchanges. For the other, we studied the relationship of the quantity of cooperator which has trade dispute and whether they sign the contract between the methods of solving the trade dispute. This research reflects the phenomena of Tianjin because basing on the data from the surveys, so it provides reference to the enterprises.

### 2. SUPPLY CHAIN PARTNERSHIP

Supply chain Partnership is the collaborative agreements of sharing information and profit, proportioning risk between enterprises. Supply chain can reduce transaction cost because of information exchange, mutual trust and fine partnership [2]. The effective partnership established by the collaborative enterprises will become the special resource and knowledge that can't be copied by others, so it is a private competitive advantage and protect the counterpart become opportunist. It's very important for all enterprise, not only manufacture but also service, to have stabile partnership. Establishing the useful partnership is the core competence for the enterprises to

enhance the satisfied level of the consumer and to achieve the win-win purpose between them by adding the product value [5].

### 3. DATA MINING AND ASSOCIATION ANALYSIS METHOD

#### 3.1 Data Mining

Data mining is an integration research field across many subjects from the late middle of 90th. It includes database system, statistics, machine learning, visual and information science [4]. Its purpose is to find out the valuable knowledge and information from huge and complex data, by analyzing the data with machine learning and statistics and storing and managing the data with database and data warehouse. The statistics is old and has exact theory, includes described statistics and concluded statistics. But the machine learning method has fewer limits and provides more comprehended result than statistics [5].

#### 3.2 Association Analysis Method

All methods of data mining are different and adapted different field [5]. Using the association analysis can find out the association rules in the data. These rules give the condition of the appearance of attribute-value in the dataset. More exactly, association rule describes the impact of the appearance of one item on the others, i.e. the interesting relation between items. It is popular in the marketing research and web analysis [5] [6]. There are also some scholars mining the text of the open question in survey.

The association rule can be formally stated as follows:

- 1) Let  $I = \{i_1, i_2, \dots, i_m\}$  be a set of literals, called items.
- 2) Let D be a set of transactions, where each transaction T is a set of items such that  $T \subseteq I$ .

3) Associated with each transaction is an unique identifier, called its TID. 4) Let  $X$  is a set of items in  $I$ . A transaction  $T$  is said to contain  $X$ , if  $X \subseteq T$ .

An association rule is an implication of the form  $X \Rightarrow Y$ , where  $X \subset I, Y \subset I$  and  $X \cap Y \neq \Phi$ . We must consider three value to be sure whether an association rule is strong:

- 1) Support  $s$ : probability that the transaction set  $D$  contains  $X \cup Y$ , support  $(X \Rightarrow Y) = P(X \cup Y)$ .
- 2) Confidence,  $c$ : conditional probability that the transaction set  $D$  having  $X$  also contains  $Y$ , confidence  $(X \Rightarrow Y) = P(Y | X)$ .
- 3) Lift [9]: the ratio of confidence to expected confidence of  $Y$ .

$$cor_{X,Y} = \frac{P(Y | X)}{P(Y)} \quad (1)$$

The rule is strong with the at least minimum support (called minsup) and minimum confidence (called minconf) and the lift is more than 1, where minsup and minconf are user-specified values.

Except for all above, a really interesting rule must have two conditions [9]:

- 1) It is exceptional and unusual.
- 2) It is potential useful.

These two conditions must be decided by the expert in the field, so the people must involve in the process of mining association rule.

Basing on the kind of the variable, the association rules can be divided to the qualitative and the quantitative. Basing on the kind of dimension in the data, they can be divided to the single-dimension the multi-dimension. In the survey, the qualitative and quantitative variable is the same, and a item correspond to a dimension, so the data is multi-dimension.

### 3.3 The Applicability of The Association Analysis Method for The Partnership

Because we use the data from survey, the reflected status of the enterprises is limited. We only use limited several items because the survey length. The relationship of the cooperation range and time between information exchanges is not casual, and the relationship of the quantity of cooperator which has trade dispute and whether they sign the contract between the methods of solving the trade dispute is not either. We just master the objective conditions. Even though there are some causal relationships between the items, these are not sufficient. We don't emphasize the

inevitable law but want express the rational correlation, so the association analysis method is suitable.

## 4. DATA DESCRIPTION

We gather data of the relation from the enterprise to the supplier or the client by the survey. The items are about the district and the contact method and how the enterprise solving dispute. These are:

- 1) The question "How the client (supplier) is distributed?" includes four answers, "in the same section", "in the same city but not the same section", "in the same country but not the same city" and "abroad". It expresses the distributing of the client and the supplier.
- 2) The question "How long the major client (supplier) has business with you?" includes five answers, "within 1 year", "from 1 year to 2 years", "from 2 years to 3 years", "from 3 years to 4 years" and "beyond 4 years". The time is longer, the relation is better.
- 2) The question "What's the method of how you connect with your client (supplier)?" includes five answers, "telephone or fax", "interview", "internet", "post" and "others". It's the information exchange method.
- 3) The question "What's the number of your major client (supplier)?" is a quantitative variable.
- 4) The question "What's the number of your client (supplier) dispute with you?" is a quantitative variable.
- 5) The question "Do you sign contract with your client (supplier)?" is a binary variable.
- 6) The question "Which method is to solve dispute?" include "go to court", "court of arbitration" and "negotiation".

There are 200 manufacture enterprises and 100 service enterprises in our sample which include big, middle and small company and different kinds.

## 5. PRE-PROCESS AND ANALYSIS

We deal with the data use the EM (Enterprise Miner) tool of the SAS (Statistic Analysis System) software after defining the question and gathering the survey data.

### 5.1 Data Pre-process

The original data is usual not designed special for the data mining, so we must revise or transform the data to the acceptable form for the mining tools. These are

clearing, integration, transforming and reducing. In this paper, we use the transforming method.

- 1) Because the original data is in the Excel table, we use the "import" function of SAS to import them in the SAS database first. There are 300 cases in the sample. Each case is a row and each item is a column in the database.
- 2) We use the ratio of the number of having dispute to the number of major client (supplier) to express whether the disputing partners are much. It's a quantitative variable. For the new qualitative variable, we must make the quantitative variable discrete before association analysis. In this paper we use the cluster to provide two new variables basing on the space partition. One is for the client number and the other is for the supplier number.
- 3) The question "How long the major client (supplier) has business with you?" has five answers. Considering the internet is widely used after 1997, so we transform to two variables using the dividing line, 1997.
- 4) The association analysis in the EM tool need transaction database, so we design a program in SAS to convert the relational database to transaction database.

## 5.2 Mining Analysis Rules In EM

The EM mining tool in SAS is a graphical operation, so it's easy to use. We just indicate the database, the variables and the analysis method. In the association analysis, the input variables are ID (transaction identify) and Item (transaction item). We identify the minsup is 5% and the minconf is 30% and the lift more than 1, so we get lot of rules. We filter the useful from all by controlling the antecedent set and the consequence.

## 5.3 Result

A perfect supply chain is involved the foundation of the collaboration between enterprise, supplier and client about the logistics and information exchange, and the foundation of the contract rule [4]. So we analyses method of information exchange and solving the trade dispute.

### 5.3.1 The association analysis for the information exchange

First, we analyses the relation between the tow items, distributing and collaboration time, to the information exchange method. Because the positive and correlative rules are interesting, so we only discuss the rules with big lift. The results are:

- 1) The companies with client on abroad and collaborated beyond 3 years mostly use the internet for information exchange. Support is 5.33%. Confidence is 34.04%. Lift is 2.55.
- 2) The companies with client on abroad have more relation with the internet information exchange method. Support is 6.67%. Confidence is 30.30%. Lift is 2.27.
- 3) The companies with domestic client have more relation with the traditional information exchange methods, "telephone and fax" and "interview". Though the lift is less, the confidence is much.
- 4) The companies with supplier on abroad and collaborated beyond 3 years mostly use the internet for information exchange. Support is 4.39%. Confidence is 34.21%. Lift is 3.89.
- 5) The companies with supplier on abroad have more relation with the internet information exchange method. Support is 5.41%. Confidence is 33.33%. Lift is 3.79.
- 6) The companies with domestic supplier have more relation with the traditional information exchange methods, "telephone and fax" and "interview". Though the lift is less, the confidence is much.

The result show that more and more companies use internet in the supply chain to contact the partner on abroad so they reduce the cost by the e-business. But the companies contact the domestic partner just use the traditional method, "telephone and fax" and "interview".

### 5.3.2 The association analysis for how they solve the trade dispute

We only consider the cases have trade dispute because most cases in the sample are no dispute.

First, we analysis the relation between the quantity of cooperator which has trade dispute and whether they sign the contract to the methods of solving the trade dispute. We only consider the rules with big lift. The results are:

- 1) The companies with more disputed client have more relation with the "negotiation" method. Support is 21.88%. Confidence is 100%. Lift is 1.42.
- 2) The companies with less disputed client have more relation with the "go to court" method. Support is 21.88%. Confidence is 37.84%. Lift is 1.27.
- 3) The companies with more disputed supplier have more relation with the "negotiation" method.

Support is 15.63%. Confidence is 100%. Lift is 2.21.

- 4) The companies with less disputed supplier have more relation with the "go to court" method. Support is 10.94%. Confidence is 46.67%. Lift is 3.32.
- 5) The companies with less disputed supplier have more relation with the "negotiation" method. Support is 28.13%. Confidence is 94.74%. Lift is 2.09.
- 6) There is no significant relation between whether they sign the contract to the methods of solving the trade dispute.

The result shows that the companies solve the dispute by tight collaboration and negotiation when they have more disputed client or supplier considering the long profit, and the companies with less disputed client or supplier tend to go to court to solve the occasional accident.

## 5. CONCLUSIONS

In this paper, we try to analyse the survey by the data mining and don't limit to the traditional statistics for the uncertain problem. We analyze the survey data from 300 samples of enterprise in Chinese Tianjin and find out a series of appropriate rules about the supply chain partnership. These rules can explain the relations between modality and measures of cooperation of enterprises reasonably and reflect the status of Chinese supply chain partnership and help the manager to make decision. So this method is suitable to the association

## Studies on Horizontal Competition among Homogenous Retailers Based on Agent-based Approach

Ming Xie, J. Chen

Research Center for Contemporary Management, Tsinghua University  
School of Economics and Management, Tsinghua University  
Beijing 100084, China  
{xiem1, chenj}@em.tsinghua.edu.cn

### ABSTRACT

This paper adopts agent-based simulation to study the horizontal competition among homogenous price-setting retailers in a one-to-many supply chain (one supplier and multiple retailers). We model the supplier and retailers as agents, and design their behavioral rules respectively. The results show that although the agents learn individually based on their own experiences, the system shows an asymptotic convergence, which approaches Nash equilibrium. Based on these results, we discuss the effects of the retailers' horizontal competition on the retail price, retailers' and supplier's profits.

**Keywords:** supply chain, agent-based simulation, horizontal competition, Nash equilibrium

### 1. INTRODUCTION

The concept of supply chain was introduced several years ago and has been widely studied in academic researches and industrial applications. A supply chain is a network composed of suppliers, manufacturers, retailers, etc., which cooperate to offer a kind of goods or service. The partners in a supply chain cooperate to gain extra profits and also compete for more profits. These cooperations and competitions, along with the various uncertainties, make the research on supply chain a quite complex and difficult task. [1] shows that in the academic study of supply chain, only some relatively simple issues are discussed, and many assumptions and constraints are imposed to these models.

Besides analytical methods, simulation is also an important research methodology. Compared with analytical methods, it is more suitable to study complex issues. Simulation has been widely applied in various engineering fields, and recently some social scientists have tried it in social science research and have got valuable results. The most prominent research in this direction is experimental economics, e.g., [2], [3] and [4].

There are also researches that use simulation to study management issues. For example, discrete event simulation [5] has a relatively long history in operations research. But such simulations are focused on the sequence and/or causal relationships of events, which is not suited to describe the competition and cooperation relationships between the partners in a supply chain. On the contrary, agent-based modeling adopts a bottom-up approach and focuses on the design of agents' individual behaviors, and watches what systemic macro behaviors evolve from individuals' micro dynamics [6]. This is quite suitable for modeling complex systems, such as supply chain systems [7].

This paper adopts agent-based simulation to study horizontal competitions in supply chains. Horizontal competition is a hot spot and also a nodus in supply chain research. It is generally analyzed with non-cooperative game theory. But just as we have mentioned before, the application of such an analytical approach is limited into relatively simple models. [8] studies a supply chain model with multiple retailers, each of whom faces a newsboy decision problem. Based on this model, [9] adopts discrete choice model to describe the dynamic process of arrival and choice behavior of each customer. As in [8], the retail prices are fixed, and the retailers only determine order quantity. We know that in many cases retail price affects customer demand. So the model in [9] should be extended to a more sophisticated model with multiple competing price-setting retailers, i.e., retailers can adjust their retail prices to influence customer demands. But this model is almost intractable with analytical methods. In this model, each retailer's profit is determined not only by his own retail price and order quantity, but also on other retailers'. The competition becomes more intense, and things become more interesting: how will these price-setting retailers make their decisions? Will the retailers find appropriate retail price and order quantity? How will the retailers' profits and the supplier's profits be? In this paper, we study such a model and try to answer these questions through agent-based simulation. We model each retailer and the supplier into an agent and design learning rules for it. The simulation results show that although the agents learn individually based on their own experiences, each of them finally gets a relatively stable policy, and the whole system asymptotically converges to an absorbing state which approaches the Nash equilibrium. Based on these results, we also discuss how the retail price and supplier/retailer profits are affected by the competitions between the retailers.

The rest of this paper is organized as follows: Section 2 describes the model settings; Section 3 shows the simulation results and provides detailed analysis; and Section 4 concludes this paper.

## 2. MODEL SETTINGS

The basic structure of the model is shown in Figure 1.

Figure 1 Model Structure

This model runs for many periods. In each period, retailers buy products from the supplier, and then sold them to customers. The supplier charges a fixed wholesale price of 1, and has infinite capacity. Every period, each retailer decides his retail price and order quantity. The products are perishable; all the unsold products are disposed with salvage value 0, and all the unsatisfied customer demands are lost. From analytical view, in each period each retailer faces a price-setting newsboy model. The only cost of each retailer is purchasing cost, occurs when receiving products from the supplier. Each retailer obtains revenue by selling products to customers. The sequence of events of this model is as follows: on each period, each retailer places an order to the supplier simultaneously; then the supplier makes enough products and sends products to each retailer with the quantity that the retailer has ordered; then customers arrive, choose retailers and buy products.

### 2.1 Customer Behavior

In this model, we adopt the discrete choice model [10] to represent customers' arrival and retailer-selecting behaviors. We assume that in each period, there is a population of customers, whose number is a Poisson random variable with mean 1000. The arrival of the customers is a Poisson process, and the service time of each customer is zero. Each customer desires only one product. When each customer arrives, he chooses a retailer from the series of retailers  $N = \{1, 2, \dots, N\}$  to purchase one product. Each customer associates a utility  $U_j$  with each retailer  $j \in N$ . In additions, there is a no selection option, denoted  $j = 0$ , with associated utility  $U_0$ , which means the utility of not purchase at all. A customer chooses the retailer with the highest utility among the series of retailers and buys a product from him. For example, if  $\text{Max} U_j = U_2$ , the customer chooses the second retailer. But if  $\text{Max} U_j = U_0$ , the customer returns home without buying anything. If a customer is not satisfied, i.e., if the retailer is out of stock, the customer makes a choice again.

The utility  $U_j$  is decomposed into two parts: one part, denoted  $u_j$ , represents the nominal (expected) utility; the other part, denoted  $\xi_j$ , is a zero-mean random variable representing the difference between  $U_j$  and  $u_j$ . Thus,  $U_j = u_j + \xi_j$ . Nominal utility  $u_j$  is determined by some identified factors. In this paper, we define  $u_j = \beta a_j - \gamma p_j$ ,  $u_0 = \beta a_0$ , where  $a_j$  is a quality index and  $p_j$  is the price for product  $j$ .  $\beta$  and  $\gamma$  represent the sensitivities of the customer to the factors. The noise part  $\xi_j$  represents the effects of those unidentified factors, and is often modeled as a Gumbel random variable with distribution

$$P(\xi_j \leq x) = \exp(-\exp(-x/\mu - \tau))$$

with mean zero and variance  $\mu^2 \pi^2 / 6$  ( $\tau$  is the Euler's constant). Here, it is obvious that the retailer with higher retail price will have less utility for a customer, and so will be less likely to be chosen.

Different with classical utility maximization, in this model we assume  $U_j$  to be unobservable a priori, so that an individual's choice is uncertain. When a customer arrives, he makes a choice based only on knowledge of the public information of each retailer's price. We also assume all the customers are homogenous, and  $\beta = \gamma = 1$ ,  $a_j = 7.06$ ,  $a_0 = 4$ ,  $\mu = 0.847$  (the data comes from the model in [9]).

### 2.1 Retailer Behavior

We model each of the retailers as an adaptive agent. Here, we first assume that each retailer has an aspiration for more profits. No matter what policy, if it can bring more profits, the retailer will adopt it, without considering its social effects.

We assume that the retailers have minimal information on the environment: they do not know each other agent's policies, payoffs and costs. All that one retailer knows is its own experiences. Also a retailer can observe other agents' historical prices, yet we assume he does not know to utilize this information under such a complex environment. Each retailer continuously learns from his own experiences, and calibrates his policies to obtain as more profits as possible. The basic idea of each agent's learning mechanism is that: each agent has an infinite set of actions. At each stage, he chooses the action that it assesses to have the highest payoff. This idea of learning has a standard implementation – the Q-learning in Machine Learning [11]. In our model, each retailer has two decision variables: retail price and order quantity. Although these two variables are generally all continuous, we assume only discrete values can be chosen. We define the minimal difference between two possible prices to be 0.1, i.e., the prices should be 2.3, 3.4, etc. We also limit retail price into the range (1, 6) (It can be tested that when price  $\geq 6$ , customers will seldom buy a product; if the price  $\leq 1$ , the retailer will get non-positive profit, which is not rational.). Thus each agent has 50 possible retail prices.

Similarly, we assume the minimal batch size of the retailers' orders is 5. We limit the order quantity into the range [0, 2000]. Then each retailer has 400 order quantity choices.

We further model each of the price and quantity decision separately into a decision "black box", which uses Q-learning algorithm to adaptively find best choices. These decision black boxes are also learning automata in artificial intelligence [12]. When a learning automaton adopts Q-learning algorithm, it keeps a  $Q$  value for each action, such that  $Q_i(a)$  represents the expected reward that the automata  $i$  believes it will obtain by playing action  $a^i$ . In this paper, we use the following formula to update the  $Q$  value of each action:

$$Q^i(a_{t+1}^i) = Q^i(a^i) + \alpha (r^i(a_1^i, \dots, a_n^i) - Q^i(a^i)) \quad (1)$$

Here,  $a_t^i$  means the action that the agent  $i$  has chosen at time  $t$ . For the actions that the agent did not choose, the  $Q$  value does not change.  $r^i(a_1^i, \dots, a_n^i)$  is the payoff the agent gets after time  $t$ ,  $\alpha$  is step size. Each automaton adopts softmax policy to choose actions based on their  $Q$  values. At beginning, each action's initial  $Q$  value is set randomly. The readers can refer to [11] for a detailed discussion on Q-learning algorithm.

Here we will make a further assumption on the decision behavior of each agent: each agent believes that it faces an environment with rather high uncertainty; it does not know when the game will be over, and it knows that it is hard to make predictions. So it does not take into account the possible future earnings. Thus the agents are assumed to be myopic, and repeatedly play a multi-person game in which all players choose actions simultaneously in each round.

### 2.3 Supplier Behavior

We model the supplier as a non-adaptive agent. In each period, she only does routine works: receives retailer's orders, produces enough products and ships them to the retailers.

### 2.4 Experiment Design

We carry out the simulation on the platform of Swarm developed by Santa Fe Institute. We use the number of retailers to represent the intensity of the retailers' competition. We select 5 representative retailer numbers 1, 2, 5, 10, and 20 to carry out the simulation one by one. For each retailer number, we run the simulation for 5 times. Each time the simulation is run for 8,000 periods to allow asymptotic behavior to emerge if it is present, and each time we use different initial action weights of each agent and different random seeds. Due to the size limitation of this paper, we will not present the program code.

## 3. SIMULATION RESULTS

We discuss the simulation results in two steps: convergence and insights.

### 3.1 Convergence

Figure 2, 3, 4, 5, 6 presents the time series of the retailers' moving average profits (time span is 20) when the numbers of retailers are 1, 2, 5, 10, and 20. The horizontal axis represents time, which is denoted with the number of time grains (There are only three numbers, 20000, 40000 and 60000. They are the time represented by time grain number. In this simulation, one period consists 8 time grains) and the vertical axis represents retailers' moving average profits.

Figure 2 Time series moving average profits with 1 player

Figure 3 Time series moving average profits with 2 players

Figure 4 Time series moving average profits with 5 players

Figure 5 Time series moving average profits with 10 players

Figure 6 Time series moving average profits with 20 players

We can see from the result data that each run shows asymptotical convergence. When retailer number is the same, different run converges to the same steady state and each retailer finally finds the same policy. For example, in the 2-retailer case, each retailer's final price has mean 2.63 with standard derivation 0.05; final order quantity has mean 399 with standard derivation 18. This

result seems self-evident due to the homogeneity of the retailers. But in fact, each retailer has its own individual decision boxes. It is quite possible that different retailer converges to different steady states, or even there is no convergence at all. In this model, each agent's initial state is not identical (each action's initial  $Q$  value is set randomly), and each retailer's learning process is also not identical (this is shown in Figure 7, which is an amplification of Figure 3's initial part). So the result of convergences reflects an intrinsic property of the systems.

Figure 7 Initial learning dynamics in 2-retailer case

This intrinsic property is that the systems have Nash equilibria, which can be approximated by these steady states.

In this model, each agent has two learning automata, one for retail price and the other for order quantity. We implement the learning mechanism of each learning automaton using Q-learning combined with softmax selection. According to [11], a learning automaton with this learning mechanism approaches best response strategy when the temperature parameter (a parameter in softmax) approaches zero. At steady states, each learning automaton converges to stationary strategies, and the temperature parameter becomes small, so each learning automaton approaches its optimal response. According to theorems on Nash equilibria, if a game with multiple players choosing their best responses converges, it converges to Nash equilibria. Then we know that all the learning automata are in Nash equilibria at steady states.

Each agent consists of two learning automata which have identical payoffs (because these two learning automata update their  $Q$  values based on the same agent's payoff value, see (1)). Then the two learning automata of each agent also play a cooperative game with the same aim of making the agent better. So, at steady states all the learning automata approaches Nash equilibrium means two things: first, each agent sticks to stationary price and quantity policies; second, each agent finds its best combination of price policy and quantity policy given other agents' stationary policies. In other words, at steady states, no agent has incentives to change its stationary policy, i.e., the agents in the game approaches Nash equilibria.

We can conduct "turbulence tests" to see whether the equilibrium is stable. Suppose when the system arrives at a steady state, one retailer suddenly loses confidence on his stationary policies, and wants to explore more efficient ones. This is implemented by changing the temperature parameter of softmax selection. We carry out a turbulence test on a 2-retailer equilibrium, and the result shows strong stability (see Figure 8).

Figure 8 Turbulence test on 2-retailer equilibrium

It is notable that during the learning process, each retailer's average profit is not always increasing. See Figure 5, there is a "peak" where all retailers' profits are higher than in equilibrium. It seems strange that the agents do not learn best strategies. This phenomenon is common in multi-agent learning. Consider the Prisoners' Dilemma, each player gets highest payoff when they cooperate, but it is not Nash equilibrium: each of them has incentive to betray given the other one cooperate. The "peak" in Figure 5 stays in the similar situation: although each retailer gets rather high profits, he has incentive to change his policy to get even higher profits. All the retailers are myopic, change policies for next period's more profits, but they are finally all worse off and approach the Nash equilibrium.

The processes of how the system arrives at steady states are different in different simulation runs. Figure 9 is another run for 10-retailer simulation, which has no prominent "peaks" as in Figure 5. But although the processes of convergence are different, the final states are always the same.

Figure 9 Another run for 10-retailer simulation

The fact that the system approaches Nash equilibrium does not mean that we are designing particular agents to find Nash equilibria. All the behavioral assumptions of the agents in this model are abstractions of real supply chain partners. We use learning algorithms to imitate the decision process of a supply chain partner who faces complex environments and with less information. The convergence means that in this model retailers will adopt stationary policies after a long period of learning and competition. This offers us a basis to investigate how the retailer price and retailer/ supplier profits are affected by the competition among the retailers: we will discuss these issues at steady states.

### 3.2 Insights

First we investigate how retailer competition affects retail prices. We get the retail prices at steady states of each simulation run, and list the data in table 1 and Figure 10 (These data and all the data in latter tables and figures are the average of 5 simulation runs, see section 2.4).

**Table 1** Retail price under different retailer numbers

Retailer Number	1	2	5	10	20
Retail Price	2.85	2.63	2.14	2.01	1.89

**Figure 10** Retail price under different retailer numbers

It can be seen that as retailer number increases (the competition becomes more intense), the retail price decreases. So customer benefits from retailers' competition. This is correspondent with intuition. Yet we observe that although retail price decreases, it does not get too low: when there are 20 retailers, retail price is still 1.88. In other words, the price war is quite mild, and no fierce lowering-price activity appears. This is because of the assumptions on agent behaviors: aspiration on more profits and myopic. Such agents will not adopt policies that decrease short-time profits to defeat other agents.

Table 2 and Figure 11 show supplier revenue under different retailer numbers.

**Table 2** Supplier revenue under different retailer numbers

Retailer Number	1	2	5	10	20
Supplier Revenue	578	800	985	1023	1044

**Figure 11** Supplier revenue under different retailer numbers

The supplier's revenue increases with the number of retailers, i.e., competition among the agents are beneficial to the supplier. The reason is as follows: retailer competition decreases retail price, so customer demand increases; accordingly, retailers will order more products from the supplier, and supplier's wholesale price is fixed, thus supplier gets more revenue.

We use following Table 3 and Figure 12 to study how competition affects the retailers.

**Table 3** Retailer profit under different retailer numbers

Retailer Number	1	2	5	10	20
Total Profit	991	1193	1010	915	806
Single Profit	991	596	202	92	40

**Figure 12** Retailer profit under different retailer numbers

Each retailer's profit decreases with the number of retailers in the market. In this model, the mean of total customer demand does not change and all the retailers share this market. The more the retailers, the smaller each market share.

Figure 12 also shows that retailers' total profit is maximal when there are two retailers and it decreases when there are more than two retailers. The decrease of retailers' total profit can be attributed to the competition among the retailers. Figure 10 show that retailer competition can decrease retail price. This has two effects: (1) decrease retailer profit directly, and (2) increase customer demand and thus increase retailer profit. Notice that in this model, each customer has the choice of not buying. Thus if there are more retailers, a customer is less likely to leave without buying anything, i.e., retailers' total profit increases. This can be viewed as the benefits of offering customers more selection options. We denote this effect as (3). General literature on supply chain management ignores this effect, yet following we will see that this effect can play an important role in certain cases. Whether retailers' total profit increases or decreases depends on the trade off between effect (1) (decreases retailers' total profit) and effect (2) plus (3) (increase retailers' total profit). From Figure 12 we can see when there are more than 2 retailers, the retailers' total profit decreases, which implies that effect (1) dominates effect (2) plus (3). Yet retailers' total profit is more in 2-retailer case than in 1-retailer case. This is different with general economic conclusions which believe a monopoly often obtains maximum market profits. Effect (3) plays an important role in the difference between this model and classical economic model, and makes effect (2) plus (3) dominate in this case.

#### 4. CONCLUSIONS AND FUTURE RESEARCH DIRECTIONS

In this paper, we investigate the horizontal competition in a one-supplier-multiple-retailer supply chain. We adopt agent-based simulation, which is quite different with classical methods. Based on the assumptions of the agents' behaviors, we endow each agent with a reasonable learning mechanism. The results show that the system converges asymptotically to steady states that approach Nash equilibria. Under these steady states, we analyze how retailer price and supplier/retailer profits are affected by the competition among the price-setting retailers, and notice the important role of customer choice behavior which is generally ignored in supply chain research.

This paper also inspires us an in-depth research on the issues of horizontal cooperation among the retailers. From former analysis we know that retailers' total profit decreases with retailer number. This gives the retailers strong incentives to collaborate with each other. We will address this issue in future work.

Furthermore, this paper inspires us to study vertical competition and cooperation in the supply chain. Here we get the conclusion that the supplier will benefit from the competition between the retailers. How things would be if the supplier can adjust wholesale price? And, when the supplier knows that retailer competition is beneficial for her, she will have incentive to prevent the collaborations among the retailers. So we can investigate what measures the supplier can take to prevent such collaborations.

# Study of Information Supply Chain and Artificial Neural Network's Related Application

Qian Li, Yongxian Wang, Youqin Zhu

School of Economics and Management, Tsinghua University, Beijing 100084, China  
{Liq1, Wangyx}@em.tsinghua.edu.cn, Zyq@mail.dzdaily.com.cn

## ABSTRACT

Users become less and less patient with huge useless data today. One of the great challenges now most net searching engines meet is how to get valuable information from lots of data sets. Aiming to satisfy every user's special demand, we need to integrate and optimize the whole course of data searching, including adjusting the users' input keywords, searching original results from network, and further processing of these results. Learning from the idea of Supply Chain Management, we put forward the concept of Information Supply Chain (ISC) in this paper to generalize the course above. For ISC's optimization, artificial neural network is chosen as a tool to find out the relationships between different keywords and paper categories, which are summarized and stored in knowledge base. Based on it, the process of selecting proper keywords and searching news information could be more efficient. A pruning method named MW-OBS is illustrated to train ANN as well. Some details about the framework and components are also mentioned, especially on how an individual step in ISC works, what's the relationship between them, and how they coordinate to meet every personal demand. ISC, an integrated information processing in the interests of users' individual need, has great advantages over simple searching from network with original keywords.

**Keywords:** Information Supply Chain (ISC); Supply Chain Management (SCM); Artificial Neural Network (ANN)

## 1. INTRODUCTION

Now days, it's difficult not to get news any more, but to find out the really needed information from so many data resources. People use searching engines to help themselves, however lots of time is wasted in distinguishing which piece is useful or not. The purpose of our study is to improve the information searching efficiency by some ways of optimization.

Some ideas about Supply Chain Management (SCM) inspire us. In productive industry, marketing rather than producing, is very important to earn profits for factories. The products who could meet the consumers' needs well will occupy an important position in related market. More and more factories put their focus on consumers' satisfaction, according to which, all business segments are recombined as well, including purchasing, producing, inventory, and selling. From 'push' to 'pull', factories assembled their working process through SCM, and this kind of optimization bring them great profits in the end.

We are wondering why not optimize the information searching process on the similar idea of SCM? Accordingly the conception of Information Supply Chain (ISC) is put forward, and more details will be discussed in the next parts.

## 2. FRAMEWORK OF INFORMATION SUPPLY CHAIN

### 2.1 How It Works Now?

<sup>□</sup>This work was supported by Natural Science Foundation of Shandong Province of China under Grant No.03BS002.

When use some kind of internet searching engine, as we always do, select some keywords casually, run the engine, then get hundreds even thousands of related results. This process could be summarized in the following chart.

About this chart, some points should be mentioned. The quality of information searching is decided by keywords, which however are chosen by users themselves without any rules. In other words, these keywords usually couldn't represent crucial characteristic attribute of the information needed. The direct impact of the results is that more useless data is got meanwhile it's even harder to find out the real needed ones.

### 2.2 "Searching Efficiency"

In order to give a pacific description of "searching efficiency", some indexes should be defined, such as 'precision' and 'repetition'

$$\text{precision} = \frac{|\{\text{Relevant}\} \cap \{\text{Retrieved}\}|}{|\{\text{Retrieved}\}|} \quad (1)$$

$$\text{repetition} = \frac{|\{\text{Repeated}\}|}{|\{\text{Retrieved}\}|} \quad (2)$$

Where "Relevant" means the quantity of the information that meets the user's demand; "Retrieved" denotes the amount of actually searching results.

The former index illustrated how much partition is useful

in all results. The later is put forward by us as a complement. It's meaningless for users to get the duplicated information, and more time is also wasted. "Repetition" is set to explain how brief and concise of the searching results.

### 2.3 The Framework of ISC

Putting more attentions to users' information demand, and assembling the related segments in processing, ISC comes into being. The segments and their interrelationships are depicted through the below chart.

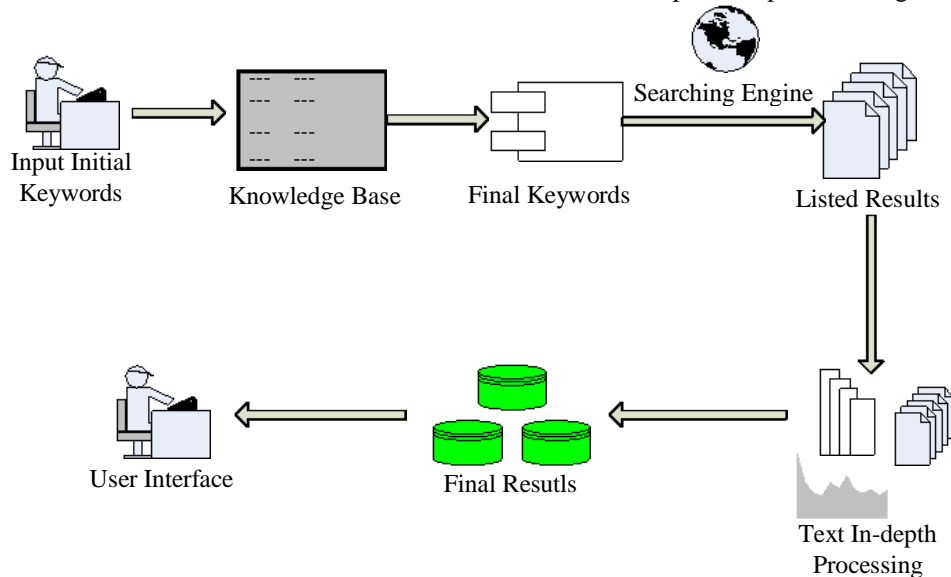

FIGURE 1 Framework of ISC

The transformation of keywords is completed through knowledgebase, in which keywords related to papers of similar categories are stored with table. A fragment is given as follows:

TABLE 1 A Fragment of Knowledgebase

Keywords	Category	Related Ones
term_1	C_1	term_1, ....., term_i
term_2	C_2	term_1, ....., term_j
.....	.....	.....
term_p	C_q	term_1, ....., term_m

Through this kind of transformation, users could expand or delete the keywords, and then strengthen the description about what they really want. For example, If we input "Stock" in any searching engine, thousands of results will come to us. To find out which one is more useful, we have to spend more time and energy. However, in knowledge base, "Stock" is related to "Corporation, Corporation Governance" in the field of "Research"; meanwhile, it is packed with "Trade, Commission, Bonus" together in package of "Finance". Users could fix on the category they are interested in, and with the help of knowledge base, "Stock" and other relative final keywords are input to searching engine, which will bring more specific results comparing to ones above. Some further text processing will be done to the listed results, including text classification, result format standardization, and so on. These are little associated to the technique we discuss in this paper, so no more description about them will be involved here. After the

processing of all steps in ISC, final results that are more concise and precise will be offered to users in the end.

## 3. ARTIFICIAL NEURL NETWORKS (ANN) IN ISC

### 3.1 About ANN

Artificial neural network is composed of a number of units, connected by weights, and it is well known about its performance on application, such as prediction, pattern recognition, machine learning, and classification. To build a neural network to perform a task, one must first decide how many units are included, how to initialize the weights of network, and which learning algorithm to be applied to a set of training and testing examples. The use of examples also implies that one must decide how to encode them in terms of inputs and outputs of the network.

### 3.2 Structure of ANN in ISC

As we have mentioned before, one of the crucial parts in ISC is how to build up a proper relationship of keywords in knowledge base. ANN is chosen as the optimization tool, and our purpose is to classify keywords according to category. Naturally, the input/output mapping in ANN is designed as keywords/categories, which determines the number of nodes in input and output layers with the layers being fully connected.

It's noticed that papers belonging to same category usually have different keywords to describe their attributes, which could be illustrated by Figure 2. Where

sample paper A has its unique keywords “ $U1...Um$ ”, and together with sample B, they both have keywords series “ $S1...Sp$ ”, meanwhile all the samples share the conjunct parts “ $K1...Kn$ ”.

FIGURE 2 Keywords Vs. Papers

Apparently, these keywords have incremental importance in classification. Correspondingly, when a given category is set as the output, these weights connected to keyword inputs should have different value, that is the main purpose of network training.

### 3.3 Representation

The output data represents the class to which each paper belongs, that is expressed as 1 or 0 indicating the class to which a paper belongs or not. In view of input data format, it is a multi volume vector where 1 or 0 means certain training sample paper has or has not the correlative feature attribute. Take example we explained in the above section, suppose three papers belonging to same category have 15 keywords in sum, the input accordingly is a 15 dimension vector. For sample paper A, on the input volumes of keywords “ $U1...Um$ ”, the value is set as 1, however about “ $B1...Bq$ ”, the value is 0.

### 3.4 Learning Algorithm

According to the characteristics of this classification task, we choose MW-OBS, a pruning method, as optimization tool, which was put forward by us in a former paper. The basic idea of this method is that it could delete weights from a trained network, whose elimination induce so little increase in error that could be ignored. In this way, it could prune those unnecessary weights even nodes, if all weights connected to which are totally deleted. Reviewing the classification problem we described above, all keywords are set as the attribute input nodes. Through this kind of pruning, the keywords with dissimilar importance to some certain category would

have different, even none connected weights to nodes of next layer, and that is why MW-OBS is chosen as learning algorithm.

### 3.5 Flowing Chart of MW-OBS in ISC Optimization

In order to illustrate how ANN is trained to satisfy the need of classification, a brief flowing chart is brought forth in next page (Figure 3) considering about the main purpose of optimization in ISC—to find out which keywords are crucial to the category. Based on such information, a knowledge base about keywords could be obtained.

Where  $E1$  is a boundary value, preventing any elimination from inducing great increase in error that can't be ignored, in other words, no more weights could be deleted. Meanwhile  $M$  denotes the number of input nodes, and  $I$  as well as  $J$  is index variable.  $N(I)$  is a parameter that represents the number of weights connecting between  $I$ th input node and nodes of next layer.  $E2$  is another boundary value for distinguishing crucial ones from all keywords. When error increase  $L(IJ)$  is larger than  $E2$ , the  $I$ th input is linked by important weights, whose elimination effects network error too much, and the  $I$ th input is regarded as a pivotal attribute to output category.

## 4. AN ILLUSTRATIVE INSTANCE

Hundreds even thousands of materials would be included as training samples in order to build up a practical and comprehensive keywords knowledge database in extent or depth, which is a huge and systemic task, and is not to be described in details in this paper. Being part of our work until now, we introduce an illustrative instance listed in table 2 considering its use in ISC.

TABLE 2 An Illustrative Instance

Keywords	Category	Related ones
Basketball	Shopping	Basketball shoes
	Sports	Basketball match, Street, NBA
	Education	Basketball English, history
	Entertainment	Basketball games

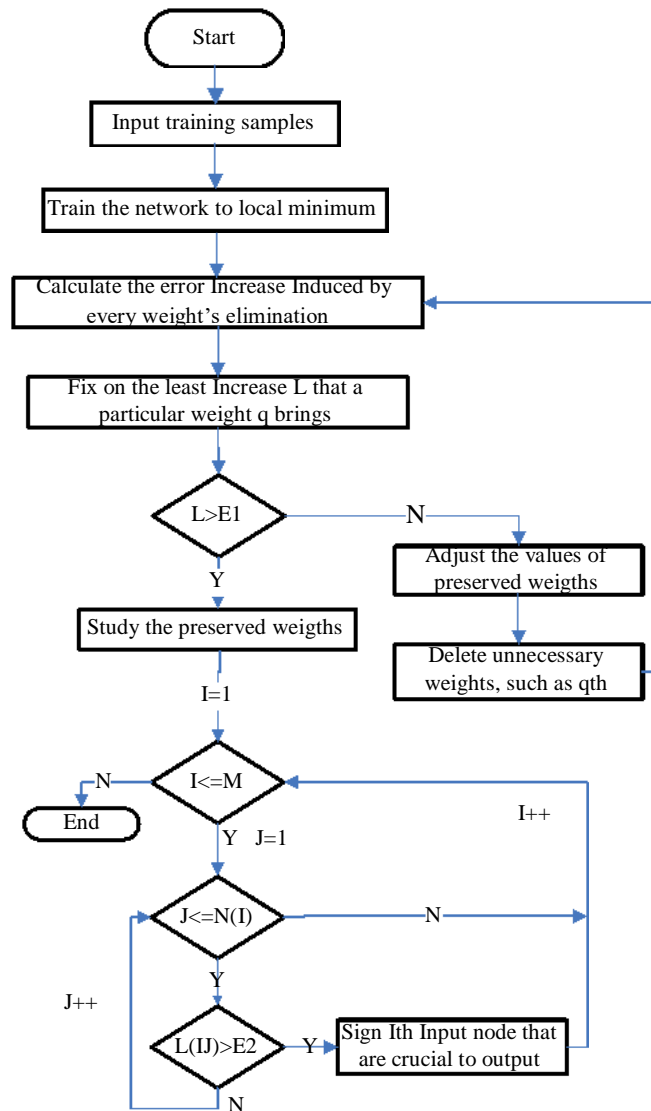

FIGURE 3 Flowing Chart of MW-OBS in ISC

About 200 paper samples are trained before arriving at these results. Reviewing the definition of “precision” offered in the previous section, several experimenters are invited to use this fragment of database to assistant their searching process and give final judgments on results. Some statistical work shows that the average precision increases near 20% through the same searching engine since more accurate keywords are chosen for searching input, and most users are satisfied with the output of ISC.

## 5. CONCLUSION

The conception of ISC is put forward not only for the achievements in technical innovation, but also to emphasis the importance of coordination in information processing. Through integrating the separated parts into Information Supply Chain, higher efficiency and precision are obtained for users' search.

With the application of knowledge base, users get final keywords, more specific and accurate descriptions than

original ones, which increase the searching precision, also help users to extend their comprehension about the related fields. Meanwhile, ISC, as a system, provides other utilities to users, such as defining logical relationship between keywords, text similarity calculation and classification. All these factors are organized and optimized in the purpose of satisfying the needs of users.

MW-OBS, a network pruning algorithm, unlike other optimization methods, deletes or adjusts the network's weight according to their contributions to net error. In the topology of ANN after training, whether the weights connected to a certain node exist or not, as well as whether the values of them are large or little, directly decides this input node is the crucial keyword or not considering the classification task.

ISC, as a new information processing solution, has shown its advantages in primary experiment, and more related research and development of it will be carried out

in the future.

## Study on Distribution Patterns of E-Business Based Agricultural Products Logistics

Yingrong Lu, Yinsheng Yang, Feng Lu, Xu Sun

School of Biological and Agricultural Engineering, Jilin University, Changchun 130025, China  
yingronglu@163.com

### ABSTRACT

The circulation of agricultural products is more complex and uncertainty than that of industrial products. The distribution channels of agricultural products are quite unique. The agricultural products logistics directly affect the efficiency of china's economy since agriculture is still main part of the economy. At the same time, with the development of information technology, e-business has affected people's daily life and brought great challenge to the traditional logistics of agricultural products. It is urgent to study the distribution pattern of agricultural products logistics under the circumstance of e-business. In fact, the platform of e-business provides a new approach for rationally deploying agricultural products. The agricultural products logistics system can be optimized based on the e-business-based distribution model. In this paper, we will focus on the logistics patterns and models of e-business-based agricultural products. After discussing the characteristics of the e-business-based logistics system, the model of logistics distribution based on electronic data interchange (EDI) and dynamic allocation mechanism will be presented. Considering the specific processes of agricultural products logistics, we depicted a framework called e-business logistics management (EBLM) model, which can integrate e-business functions and distribution functions. Finally, we will discuss the implementation strategy of EBLM.

**Keywords:** *agricultural products logistics, E-business, distribution patterns, EBLM model, implementation strategy*

### 1. INTRODUCTION

The characteristic of the information society is the optimization of information flow and IT-based innovation. The development of the Internet provides such a tool that is changing the market rules and forming the new network economy. As the representative of network economy, E-business has already been applied in nearly every aspect of our social activities, such as retail, service, manufacturing, etc. Especially, Internet has changed the operation behaviors of enterprises thoroughly. Annam, the general secretary of the United Nations, said that e-business is pushing the economy development, improving the trade efficiency, and enhancing the competition ability of enterprises. It can not only integrate the national economy into the world economy, but also can provide the employment opportunities and create more wealth.

Although we still cannot predict when the e-business dominated trade will become the primary trading mode, the potential of the e-business market is endless. According to the U.N. E-business Development Report in 2002, the number of global Internet customers has reached 6.5 billion by the end of 2002<sup>[1]</sup>. In China, the number has reached 87 million by the end of June in 2004 according to the latest investigation report from the China Internet Network Information Center (CNNIC). On the other hand, the volume of e-business trade grows fast. Forrester, a famous consultation company, estimated that the volume of global e-business trade in 2002 is about 2,293.5 billion USD, and it will attain 12.8 trillion USD in 2006, which will be 18% of the world retail volume, and the average growth rate is

above 30% each year. In China, The U.N. E-business Development Report in 2001 indicated that the volume of B2B and B2C market would be 4 billion USD in 2003, B2B would increase 194% each year, and B2C will be 274%. Due to intensive labor force in agriculture, the development of e-business of agricultural industry is more difficult than other industries. Although the agricultural circulating network has developed at certain level in our country, and some regions such as southeast area has already started to construct the e-business-based agricultural products system, there are no systematic planning because of lacking corresponding theory. A lot of research works have been done about seasonal products<sup>[3][4]</sup>, but there is still no special concern about agricultural problems. For the information-based agriculture, it is very important to improve the circulation of agricultural products under the e-business environment. That is why we will study the e-business-based agricultural products logistics patterns in this paper.

### 2. THE FUNCTION OF THE LOGISTICS DISTRIBUTION IN E-BUSINESS DEVELOPMENT

The logistics distribution is a very important link that completes the whole e-business-based trade.

#### 2.1 Modern logistics is the basis of e-business

Each e-business trading process generally needs three essential elements: the logistics, information flow, and cash flow. The logistics is the foundation; the information flow is the bridge; and the cash flow is the

purpose. Each e-business trading process usually accompanies with the logistics and information flow. The trading partners need information so as to send out, follow, divide, receive, store, pick up and pack the goods, etc. In information era, the cooperation of logistics and information flow becomes extremely important, and must be supported by modern logistics techniques.

Logistics techniques refer to the general name of all professional techniques related to logistics elementary activities, including various working techniques and management skills such as circulating machining technologies, packing technologies, identification technologies, real time tracing technologies etc. With the development of computer network technologies, logistics technologies synthesized a lot of modern information technologies, for instance, GIS, GPS, EDI, Bar code, etc. The logistics industry accelerates to use the modern information technology. This will pave the way for the popularization of the electronic commerce.

## 2.2 The logistics distribution system is the supporting system of the e-business

Modern logistics distribution can provide service for the customer of the e-business. According to the characteristics of e-business, it can implement the unified management of the information, schedule the whole logistics distribution system, complete to manage the goods at the request of customers, and send goods to the consignee. This logistics mode is significant to logistics enterprises for improving the service quality, reducing the logistics cost, raising enterprise's economic benefits and social benefits.

## 2.3 The logistics distribution system improves the efficiency of the social economy circulating

The logistics enterprises adopt computer network technology, application software systems and advanced management theory, according to the customer's demand, they carry on a series of arrangements, such as classifying, allocating, ordering, dividing, mixing goods, etc., to deliver all kinds of goods in right time, right place and right quantity. The new logistics model becomes the pioneer in the field of circulation, and represents mainstream of modern marketing. On the other hand, it is easier to realize informationization, automation and socialization in the new logistics system than in the traditional one. It can not only reduce the stock of manufacturing enterprises, accelerate the turnover of the fund, improve logistics efficiency, reduce the logistics cost, but also can stimulate the social demand, promote the sound development of the economy.

## 3. ANALYZING THE CHARACTERISTICS OF AGRICULTURAL PRODUCTS LOGISTICS DISTRIBUTION

### 3.1 The characteristics of agricultural products logistics distribution

After China re-entered world trade organization (WTO), the bulk agricultural products of China, such as cereals, oil, cotton and sugar, will be in a inferior position in international market and the production cost is obviously higher than the same agricultural products price in international market. But for the labor-intensive agricultural products, such as vegetable, meat, birds, eggs, as well as aquatic products, it will be in a superior position both in amount and price. The market mechanism of agricultural products has been a certain scale in our country. We focus on the study about logistics system of agricultural products here.

For agricultural products, the logistics chain is depicted in Figure 1.

Figure1 agricultural products logistics chain

In Figure 1, the preparation of production includes planting seed industry, feed industry, information guidance, products planning, etc.; agricultural production includes field management, instructor, fertilizer planning, etc.; agricultural products process includes grade classify of products, packing, fresh-keeping, storage, etc.; the circulation of products includes channel planning, a network of commercial establishments laying out, circulation technology of cold chain, market building of product and sale, etc.; consumption of products includes providing enough variety and quality of goods, guiding consumption, etc..

Agricultural products logistics chain includes all links and procedures from cultivating seed to field management, agricultural products processing, keeping fresh until circulation, market sell. Each link on the chain is related with many other industries, and such basic elements as agricultural science and technology, agricultural information and standardization etc. are influencing the agricultural industry chain, the distribution network that takes agricultural production as the main thread will be formed finally. What it pursued is to form various mechanisms to realize the goal of resource rational distribution.

The characteristics, such as localization, seasonal cycle, scattering etc., are very outstanding, meanwhile, the agricultural products are people's everyday necessities, the consumption elasticity is low.. The several characteristics exist in the whole logistics include:

### 1) The dispersion characteristic of produce distribution link

The producing area of agricultural products is very wide. The production unit, such as farmers, does not understand the market information and lack of essential production planning, thus the production link becomes the most difficult to control in the whole logistics chain. Dispersion characteristic of production leads to dispersion of the front logistics in the industry chain.

### 2) The region characteristic of circulation distribution link

Agricultural products are widely produced in different regions, and people's demand is diversified, therefore circulate trade occurs in different areas. But because agricultural products are fresh and perishable, even if we take measures to keep fresh, they will still have some proportion loss, and this proportion will be strengthened with time and distance running up. With the circulate cost rising, the radius of the agricultural products circulation is restricted. On the link of the fresh products delivering, keeping cold and keeping fresh of the fresh products and the cycle of the process have restricted in the supporting service radius of the center. This is obviously different from the normal temperature logistics.

### 3) The specified distribution facilities

Because the agricultural products are fresh and perishable, we must take some measures in circulating, so that agricultural products could be consumed with high quality. Some variety specific container and equipment will be needed<sup>[2]</sup> in the course of agricultural products warehousing and transportation. The cost of agricultural products logistics distribution should be higher than the traditional industrial products, so extensive and specialized management will be needed.

### 4) Integrative characteristic of delivering and trade (the trading process accomplished by distribution)

In recent years, our country builds 3-level marketplaces for agricultural products circulation, namely the wholesale market of agricultural products in producing region, the wholesale market in selling region and the retail market of farm and produce. The 3-level wholesale markets take not only the function of the trade but also the functions of the delivery. It is showed that agricultural products logistics will be difficult to exist independently when it break away from the trade center.

We can see from these characteristics that the agricultural products logistics chain is different from industry's logistics relying mainly on production, its key link lies in circulation that will drives the operation of the whole logistics chain.

## 3.2 the key problems and solutions of agricultural products logistics distribution

Our country has always pays attention to agricultural products circulation system. According to the characteristics of the agricultural products logistics distribution, our country comes on quite loose policies and regulations for encouragement to set up modern agricultural products logistics system. As the foundation of agricultural products logistics is relatively weak, we still face a lot of problems now. Considered the whole logistics chain, the key problems among them include:

### 1) Strategy positioning of the agriculture products logistics

In the field of agricultural products circulation, there is still lack of the concept of the whole logistics system at present. The operator on each link is often engaged in the commercial activity taking oneself as the core. In terms of the logistics strategy of the whole industry, the end of logistics chain-consumption- is emphasized. Therefore the development of agricultural commerce centers and fresh food supermarket are fast, but it can't drive other links in the chain.

### 2) Lacking flow of the information in the logistics chain

Rational flow of the information is even more important in the efficient logistics chain, that is, there should be a valid information share mechanism among each link in Fig. 1, which can improve the operation efficiency of each link. But so far as the present situation in our country, mechanisms which can collect, store, analyze and use information of agricultural products logistics chain have not been set up. The incompleteness and dissymmetry of information results in blindly and inefficient production. Poor information also leads to the existence of a large amount of invalid logistics. According to statistics, agricultural products' losses in the course of circulation are probably 75 billion to 80 billion every year in China, accounts for 20% of the output value.

### 3) Lacking the unified planning of logistics distribution system

Region and dispersion characteristics of agricultural products make it is difficult to manage and plan logistics distribution. Up to now, we have not set up rational planning method yet. Trans-regional fresh products logistics, because its loss is heavy and its costs are high, whose scheduling is more unable to realize.

For these questions, the government of China has responded correctly, six government ministries jointly point out in 2003: the agricultural products circulation facilities are an important component of the social infrastructure. And the report further defined the strategic position of agricultural products circulation. Under the guidance of this policy, we can solve three key problems mentioned above from three following aspects:

### 1) Focusing on circulation, build up strategy of the

agriculture products logistics chain

The idea of agricultural products supply chain management should be spread. At the same time, the traditional logistics chain, which taking consuming as the core, should be transformed. Actually, circulation link is the most potential part of the supply chain, so the new strategy should be based on circulation, and the function of the circulate link should be enhanced correspondingly. In detail, based on the traditional collecting and distributing center and new e-business environment, the circulation part should has functions such as production guiding, trading and information management etc. The strategy with circulation as the core will fully utilize e-business environment, contribute to overcome the disadvantage of decentralized agricultural production.

2) Improve information collection and analysis among logistics chains, strengthen the information function of the traditional collecting and distributing center (CDC)

The communication and coordination of information are important foundation of the modern logistics management. Information management in the CDC should be further strengthened after the center of the logistics chain is transferred to the circulation link. The e-business trade platform of agricultural products will be set up on the basis of setting up two levels collecting and distributing system, namely, CDCs in producing area and selling area. On one hand, the information of production, demand and relevant information on the logistics chain will be classified, stored and shared. On the other hand, the trans-region scheduling of the

agricultural products will be realized by the information analysis function. Based on the analysis of demand information, the agricultural production will no longer be blind also.

3) Based on e-business environment, set up new management systems of so-called e-business-based integrated agricultural products logistics  
E-business technology and the derived methods of logistics management is the foundation of our new logistics strategy. On the basis of fully considering the characteristics of logistics and information flow in the course of agricultural products circulation, we will set up an integrated e-business-based agricultural products logistics management models.

#### 4. E-BUSINESS-BASED LOGISTICS MANAGEMENT (EBLM) MODEL FOR AGRICULTURAL PRODUCTS

As we mentioned above, the key of solving agricultural products logistics problems is to establish an e-business-based platform that logistics and information flow are considered and integrated. This platform has not only traditional wholesale functions, but also new Internet-based functions such as electronic trade, logistics management, information share, balance of supply and demand and production planning, etc. Aiming at this goal, we will establish an E-Business-based Logistics Management (EBLM) Model for Agricultural Products (figure 2).

Figure 2 E-business-based Logistics Management Model for Agricultural products

In figure 2, the wide arrows indicate logistics and narrow arrows show information flow. The EBLM model is

composed of 3-level supply chains: agricultural products processing unit, distribution & wholesale center and retailers. The third party logistics will be fully used to fulfill transportation of agricultural products among 3-level supply chain. The functions such as information share, online trade, and schedule optimizing and market prediction will be realized by setting a platform of e-business.

Specifically, agricultural products processing unit is made of farmers, processing factories, farms and importers, which are headstream of logistics and production information provider. As noted previously, agricultural products processing unit in our country has been dispersed, but if we set up the portal system of the regional distribution center, information can be exchanged conveniently on the portal among these processing units. This will solve various kinds of problems because of scatterance. In addition, processing unit will emphasize pre-treatment of the agricultural products according to the demand information, which will effectively lower invalid logistics.

Distribution & wholesale center (DWC) is physical center and information node. It combines the functions of traditional wholesale markets both in producing area and sale area. Different centers may have different functions according to the characteristics of the physical region of the center. Meanwhile, in this center, the two databases: agricultural products database and logistics database, and a portal website will be set up also. In the portal website, the third party logistics can be scheduled and agricultural markets trends will be analyzed. In addition, the center is the hub of downward information flows, and agricultural products processing units can get direction from the analyzing function of the portal.

The retailer is composed of farm produce marketplaces and supermarkets. It is the end of EBLM and faces to consumers directly. The retailers get agricultural products through the coordination of e-business platforms, distribution centers and the third party logistics. An important function of retailer in the model is the collection of the market information. On the basis of the statistical analysis of sales information, it fixes the general market trend and formulates the corresponding purchase plan, then offers information to the e-business trade platform.

The e-business platform is a virtual center of EBLM, which can be operated independently or based on a certain DWC. The platform connects all DWCs to realize information share in each link of agricultural products supply chain, schedule trans-region logistics, deploy limited transportation ability, such as rational utilization of cold chain circulates ability etc..

## 5. IMPLEMENTATION STRATEGY OF EBLM

The EBLM model has compressed the length of the

traditional agricultural products supply chain by the virtual and physical centers, and strengthened the functions of information share and analysis among every links of the supply chain. This model can improve the efficiency of the agricultural products circulation effectively, reduce circulation cost and contribute to realize strategic idea to set up of new agricultural products circulation system. However, the foundation of the application of agricultural information technology is still very weak, the third party logistics is not developed enough in China either, so it's difficult to implement the EBLM.

In order to implement EBLM smoothly, firstly, we should do the unified planning of the agricultural products circulation facilities, and should prevent repeated construction. The government in policy and in certain regular range should guarantee the unified standards about implementation of the EBLM. The unified planning will contribute to preventing from malignant competition and setting up normal environment of agricultural products circulation.

Secondly, the construction of the agricultural products market's information network should be strengthened. The Ministry of Agriculture has already done the work in this aspect, some agricultural products information networks are running and releasing information now. But the functions of these systems are limited and need further improvement. On the request of EBLM, the agricultural products e-business platform is relatively centralized and simple, so we should adopt the standard component, thus it can lower costs by a large and popularize rapidly. Another focus is how to set up database system, including the mechanism of data collecting, processing, storing and using.

Thirdly, the rational implementation tactics step by step should be constituted. The infrastructure of agricultural products logistics should quickly be constructed at present to promote trans-region circulation of agricultural products and cross-seasons supply and to guarantee the market supplies. Agricultural products logistics in main producing region and main demanding region should quickly be set up, especially for western food to eastern area. The peasant's cooperative transportation organization and large management enterprises should be fostered to guide actively and encourage peasants to transport and sale agricultural products together. This is the basis of forming DWCs. The agricultural products management enterprises should be supported to build some circulation facilities to preserve transport agricultural products. We should strengthen the ability in transport and selling, expand business scale and develop made-to-order farming to improve the organization efficiency in China. Based on the analysis above, the cooperative society and the agricultural products management enterprises should be turned into progressively distribution center of EBLM, these are DWC.

Fourthly, the multi-channels social funds for the development of EBLM are encouraged. Government will encourage, enterprises and individuals to attend agricultural products circulation system construction. The trans-region development logistics distribution and catenation management should be encouraged. The current management system of wholesale marketplace should be reformed to set up the new operating mechanism in which the real investors will get the real benefits, and they will assume sole responsibility for its profits or losses.

Finally, the circulation should open to the world. The involvement of foreign partners can improve the transportation capacity and management level of the logistics industry in China so as to promote the implementation of EBLM model.

In addition, the state's policies should be fully utilized. Our country will arrange some allocating funds every year during the Tenth Five-Year Plan period to subsidize the information system of agricultural products market, pesticides residues monitoring system and electronic settlement and infrastructure such as the roads, marketplaces, etc.. The local government must also offer certain related funds to the project that the central government supports. In the view of this point, The National Development & Reforms Committee issued a document called "the notice on printing and distributing pilot project implementation suggestion of wholesale market of agricultural products of 2003"<sup>[1]</sup> in April of 2003. In this document, central government will arrange more than 400 million RMB national debt funds to support 81 projects. Majority of them is the marketplace, others are agricultural products storing and fresh-keeping enterprises. At the same time, the government will continue implementing the supporting policies, such as bank loans, finance pays interest etc.. Taking the year of 2003 as an example, projects on agricultural products circulation, including HuaLian and LianHua supermarket in Shanghai, gained more than 10 billion RMB loan with low interest.

Based on EBLM, agricultural products circulation system can be set up by the country's support, enterprise's participating and rational implementation tactics.

## 6. CONCLUSION

With the development of information technologies, there

is a strong tie between modern logistics and e-business. It is important to develop an integrated e-business-based logistics system. In this paper, the problems of the e-business-based logistics of agricultural products are explored, and the characteristics of agricultural products logistics distribution are analyzed also. In order to solve the problems in the traditional agricultural products logistics, the e-business-based agricultural products logistics management model (EBLM) is put forward and the implementation tactics are discussed also.

Agricultural products logistics in China has great potential. The operation efficiency of the whole agricultural products supply chain will be improved effectively by setting up e-business logistics system with circulation as the core. Under the guidance of this strategy, implementing EBLM model can carry on effective management to logistics and information flow in the agricultural products supply chain so as to set up normal and efficient agricultural products circulation network.

In order to implement EBLM properly, a systematic approach should be adopted, and get the support from the governments, enterprises, and farmers.

Further research will focus on the analysis of the issues involved to the EBLM from macro and micro views, for example, the study of macro policies of EBLM, the construction scheme of e-business platform, information standard and share mechanism, etc..

## ABSTRACT

Electronic commerce has been changing the operation models of firms to adjust the ever more competitive environment in the commercial field, and the new ones of cooperation among firms have been formed by it. In the globalized electronic commerce, the old and traditional models of supply chain management have faded away by being failed to fill the needs in the electronic commerce, and the new models of, therefore, should be created. Firms strive to adapt their supply chains to the electronic commerce, and they need to decide how much and in what sequence they will be investing in various supply chain efforts to leverage the benefits of the new technology. In this paper three main aspects are described. First, based on the present a comprehensive definition of supply chain management, relevant characters of it that have risen to the importance with the prevalence of electronic commerce are provided. By using the universal criteria in the Internet, the information in many directions being flowed has been already realized, so, the commercial partners can build a automatic and integral supply chain, and the chain can operate as a whole. Second, the strategies of implementing supply chain management are discussed. By applying the supply chain management in electronic commerce, the time of communication between companies has been shortened; the nicety has been realized; and the efficiency of stock and conveyance has been greatly improved. Moreover, by integrating multi-enterprise, the implementations of concurrent engineering and inventory-reinforce plan have been allowed.

**Key Word:** Supply Chain Management, Characters, Strategies, Electronic Commerce

## 1. INTRODUCTION

The rapid growth and adoption of the electronic commerce have already had a great impact on all aspects of business, including customer acquisition, marketing, human resource management, finance, information systems (IS), and operations. Supply chain management that has played an important role in traditional businesses is likely to be crucial in the electronic commerce environment as well<sup>[1]</sup>. To survive in the competition, the companies have, especially for someone who compete in the low technical-obstacles industries, have to be closely connected with whole-sellers, dealers and retailers to reduce the cost of products and to gain a competitive edge. At during the next five years, collaboration by supply chain partners over the electronic commerce can potentially save \$223 billion with the reduction in transaction, production, and inventory costs<sup>[2]</sup>. This could be one of the largest benefits of electronic commerce technology and many firms have already begun to realize these benefits. For example, Microsoft used a Web collaboration tool to bring the Xbox video game console to market two months ahead of schedule<sup>[2]</sup>; Cutler-Hammer has doubled profits and increased productivity by 35% for its configured motor control centers and control panels by coordinating with customers over the electronic business<sup>[3]</sup>; and Autoliv reduced the plant inventory by 37% by coordinating orders online with suppliers<sup>[4]</sup>. The large potential impact of the electronic commerce on supply chain management makes its study timely and important.

## 2. SUMMARIZE OF SUPPLY CHAIN MANAGEMENT AND THE E-COMMERCE

### 2.1 The Conception of Supply Chain Management

Having a concrete understanding of supply chain management, which has been enriched in the trend of globalization of production and service, is the precondition to success of operating it. Then, what is the supply chain? A supply chain is the set of entities (such as whole-sellers, producers, retailers, transportors, and final consumers etc.) involved in the design of new products and services, procuring raw materials, transforming them into semifinished and finished products, and delivering them to the end customer. Supply chain management is the efficient management of the end-to-end process, which starts with the design of the product or service and ends with the time when it has been sold, consumed, and finally, discarded by the consumer<sup>[5]</sup>. This complete process includes product design, procurement, planning and forecasting, production, distribution, fulfillment, after-sales support, and end-of-life disposal. The utility of supply chain management is to boost the cooperation between many entities, including whole-sellers, producers, retailers, transportors, and final consumers. The cooperation, which enables to optimize all the relations concerned with the supply chain, thus, provides the biggest value to buyers by minimizing the cost.

It is clear that supply chain management spans several functional and geographical areas, introducing

complexities both in terms of design and execution. Some of the pertinent factors that complicate supply chain management decisions include the presence of multiple agents and their sometimes conflicting incentives; uncertainty in demand, supply and production distribution process; asymmetry of information related to product design, inventory, costs, demand and capacity across the supply chain between the various parties in the supply chain; and lead time between the different entities in the supply chain. All these complexities lead to several types of inefficiencies in the supply chain: poor utilization of inventory assets<sup>[6]</sup>; distortion of information such as the bullwhip effect<sup>[6]</sup>, high stock-outs and nonresponsive supply chains<sup>[7]</sup>; poor customer service due to customization-responsiveness challenges<sup>[8]</sup>; and double marginalization that leads to lower profits for the supply chain<sup>[9]</sup>. Setting up models of supply chain management for electronic commerce in the ever developing environment is the guarantee of successful implementation.

## 2.2 The Conception of Electronic Commerce

Why electronic commerce can be loosely defined as IC (Internet Commerce) is because the electronic commerce process is developed by the technologies, mainly by using EDI and the Internet or other electronic medium as a channel to complete business transactions<sup>[5]</sup>. Therefore, all the ways of exchanging information, which was not used to be transformed by Internet, are completely changed by doing it in the supply chain. They enables the scarce resources to be fully applied, the commercial taches and time period to be abridged, so, the cost cutting, efficiency rising, quality reinforcing are all realized.

Electronic Commerce consists of three areas<sup>[6]</sup>: (1) consumer-oriented activity and (2) business-oriented activity supported by (3) the electronic commerce technology infrastructure. The technology infrastructure relates to network infrastructure, network applications, decision technologies, and software tools and applications.

## 3. CHARACTERS OF SUPPLY CHAIN MANAGEMEN IN ELECTRONIC COMMERCE

Internet has created opportunities to integrate information and decision making across different functional units, thereby creating a new channel for companies and buyers in supply chain that go beyond a business unit to study the extended enterprise<sup>[5]</sup>. Supply chain management has coordinated the relationships among departments and the members in the supply chain. By applying more simple, fast, and much lower cost E-communicating way contacting whole-sellers, retailers, producers, and buyers, the relationships among departments and members in the supply chain

have been coordinated. Thus, electronic commerce has greatly elevated the role of supply chain management and analysis within a firm, and made it with the unique characters.

### 3.1 The Information Sharing Fully

Internet has also opened up opportunities for firms to share information and efficiently coordinated their activities with other entities reinforced in the supply chain. Integration of important data in the supply chain by fully sharing information is the guarantee to provide undistorted and timely information.

### 3.2 The Synchronization of Supply Chain

In the supply chain management process, companies establish more effective ways of E-communication by applying E-mail, E-meeting, E-marketing, and database integration, and intagrating information systems among firms to make sure that all the nodes in the supply chain are accessed information at the same time. Therefore, the synchronization of the supply chain is realized.

### 3.3 The Integration of Supply Chain Management

Supply chain, with producers, whole-sellers, retailers and buyers, enables companies and other related organizations connected into a net, in which all units form a concrete strategic relationship based on sharing the universal benefits and harms<sup>[10]</sup>. Since the shared information is unlimited by time, space and the increasing flow of it, the pattern of information transaction has become a net too. Thus, all the units in the net can trust eath other more, and form a strategic alliance. The integration of suply chain management, therefore, is boosted.

### 3.4 The Innovation of Business Process

Supply chain managemen in electronic commerce has changed many aspects of business process from purchasing to logistics<sup>[11]</sup>. This change needs every units in the supply chain, especially the core members, to operate the internal BPR (business process reengineering) from a macro-coordination. To realize the changes of business process, innovations have been made to adjust the needs of higher efficiency and flexibility for supply chain managemen.

### 3.5 The Speed of Operating Suply Chain Management

Being back up by the Internet technologies, the supply chain management enables all members in the supply chain to reduce the unnecessary and nonprofit steps of the process to cut the cost. This is the ensuring to the realization of promptness and fineness.

#### 4. THE STRATEGIES OF IMPLEMENTING SUPPLY CHAIN MANAGEMENT IN ELECTRONIC COMMERCE

To make sure the success of implementing the supply chain management, a suit of strategies should be established.

##### 4.1 The Establishing Basic Components for Supply Chain Management

Supply chain management is the combination of art and science that goes into improving the way in which your company finds the raw components<sup>[12]</sup>. Supply chain management needs to make a product or service, manufactures that product or service and delivers it to customers<sup>[13]</sup>. The following are five basic components which are established for supply chain management.

**4.1.1 Plan-**This is the strategic portion of supply chain management. You need a strategy for managing all the resources that go toward meeting customer demand for your product or service. A big piece of planning is developing a set of metrics to monitor the supply chain so that it is efficient, costs less and delivers high quality and value to customers.

**4.1.2 Source-**Choose the suppliers that will deliver the goods and services you need to create your product or service. Develop a set of pricing, delivery and payment processes with suppliers and create metrics for monitoring and improving the relationships. And put together processes for managing the inventory of goods and services you receive from suppliers, including receiving shipments, verifying them, transferring them to your manufacturing facilities and authorizing supplier payments.

**4.1.3 Make-**This is the manufacturing step. Schedule the activities necessary for production, testing, packaging and preparation for delivery. As the most metric-intensive portion of the supply chain, measure quality levels, production output and worker productivity.

**4.1.4 Deliver-**This is the part that many insiders refer to as "logistics." Coordinate the receipt of orders from customers, develop a network of warehouses, pick carriers to get products to customers and set up an invoicing system to receive payments.

**4.1.5 Return-**The problem part of the supply chain. Create a network for receiving defective and excess products back from customers and supporting customers who have problems with delivered products.

##### 4.2 The Process of Implementing Supply Chain Management in Electronic Commerce

##### 4.2.1 Setting Up the Companies' ERP/MIS System.

The units in the supply chain, especially the core members, having the mature informational system, means that all the members in the supply chain have the smooth of informational flow and the internal business process, and that they can apply the connecting system of the upstream facility and the downstream facility to ensure the realization of smooth the business process. The mature and concrete informational system in a company, therefore, is the precondition for the successful implementation of supply chain management in electronic commerce.

##### 4.2.2 Making Coordination Project between Upstream Facility and Downstream Facility in the Supply Chain.

Once the project is begun, its team should be organized by all units to confirm the technological criterion, platform, exchanging necessary data and database format together. For different units have different database format and different products' code, a transforming system according to them should be set up to let all units to be freely accessed to the utility of the supply chain. After the coordination project and the timetable are built, every unit in the supply chain is required to develop their Web Service according to itself criterion.

##### 4.2.3 Applying the BPR for Logistics or Business Process to Meet the Requirement of Supply Chain Management in Electronic Commerce.

How much the supply chain management could benefit a company depends on how much the operating models of the company could adjust the informational needs. The desired effects of the supply chain management in electronic commerce could not be embodied, even the benefit would be cut off by the failure of coordination between both sides, if the systems between upstream facility and downstream facility in the supply chain are connected only, but the business process with it is not changed. For this reason, a full analysis of business process should be done firstly, the unefficient process deleted and integrated, and the business process redesigned to meet the need of coordination of the supply chain.

##### 4.2.3.1 The Innovation of Business Process within A Firm.

Helped by the advanced information technologies and the thoughts of supply chain management, the internal business process of a firm has made great change<sup>[11]</sup>. Take the relation of the business process between producing departments and purchasing department as examples. Under manual manipulation conditions, the model of sequacious engineering was applied, in which the production plans made by the firm's managers, programed by the departments to supply raw materials, asked for permission from many layers of an organization, and sent the order form to suppliers after above works done. Because the prolonging process and involving too many departments and people form out of joint, holdup and repeat, a

project would always be done through a long time. In the supply chain management, however, the original business process can be synchronized its steps and largely simplified by sharing database in a high-tech platform of information, which makes the original model of sequacious engineering transformed to concurrent engineering. For instance, the purchasing supply department can make its decision promptly by acquiring the plans according the information on the database after producing departments finishing the producing plan, by counting the raw materials consumed necessarily and suitable parts. Furthermore, the order form can be sent directly to the suppliers through Internet or EDI in the supply chain.

Anyway, the innovation of internal business process is to meet the needs of the coordination in the supply chain, and to realize the informatinal management of whole process in the line, which embodies its effects by the intensivism of information, by the simplifying and the adjusting a firm's internal business process, and by reducing the middle-level management and many complex taches.

**4.2.3.2 The Innovation of Business Process among Firms.** Under the circumstance of applying supply chain management, the business process has been made much easier by the application of Internet or EDI, for many business taches done by manure labor in the past are made unnecessary or even erased with such the more modern way as E-commerce. For example, suppliers were used not to prepare for producing until receiving the order form from buyers, and after the parts being ready, so much time had been wasted. The whole producing process would be much prolonged in such a vicious circle. Under supply chain management, however, all firms are accessible to the freshest information of the production schedule to make better and timely decisions for production, supply, and delivering with Internet. At the same time, a supplier who knows the condition of consumption on the buyers' side by being informed from Internet, is capable to shorten the period of supply goods, especially during the time that the stocks are full, , and makes a full preparation before not receiving the orders from manufacturers so that the cycle is largely shortened. Because of this more effective way of coordination, the original departments, positions, and processes, which are for the jobs that can be simplified, can be considered to re-design.

The innovation of business process among firms based on the innovation of business process within a firm alter ulteriorly the business process among members in supple chain so that responses to the customers are shortened and the stronger feeling of satisfaction will be realized.

**4.2.4 The Strategy of Integration Web Service Concerned with Firms to the System of Connection.**

The connection between the upstream facility and downstream facility in the supply chain based on the Internet makes the concerned firms to freely exchange information, and the works of debugging and test followed the exploitation of the system operated.

**4.2.5 Acquiring the Support and Cooperation from the Parners.** Different from the innovation of business process within a single firm in supply chain, the innovation of business process among firms are much more difficult for changing not only the business process within a firm but also other firms', including operating interosculation and keeping touch with suppliers and distributors. Therefore, in desired condition, the innovation of business process of supply chain management should be set out from a macro prospective, and all the nodes should be synchro-reformed. In other word, the whole harmony among units, especially jointing firms in the supply chain, is the most important point, though the situations in different firms are different. Otherwise, the coordination of the supply chain would not be promised.

**4.2.6 The Evaluation to the Supply Chain Management in Electronic Commerce.** It is necessary to harmonize the operation models among all units of the supply chain, and to adjust the data platform to meet the realistic need in time by the evaluation to the supply chain management.

## 5. CONCLUSION

With the rapid development of electronic commerce and the fierceness of competition, supply chain management will have brought ever greater profits on firms<sup>[14]</sup>, provided better services and more greater values for customers, and griped more worthy opportunities of the new market in order to make give the firms an advantage over in the fierce competition<sup>[15]</sup>. The paper shows the characters of the supply chain management in electronic commerce, which can fulfill the requirements of low-cost and flexible, and the models are applicable for many companies. As long as the problems of safety, financial ability and technology could be ensured settlement, supply chain management in electronic commerce will be made sure to embody the imponderable advantages, especially in sharing information and concurrent engineering, to be comparable to the traditional management of supply chain, and become a prevalence in the near future as a new and exciting management model<sup>[16]</sup>.

## ABSTRACT

This paper considered a single-item, three-echelon (supplier, retailer, and customer) inventory problem. At random times, the supplier offers the retailer a discount. The inter-arrival times of discounts are exponentially distributed. For the retailer, whether or not to take a discount offer depends on its inventory level. If inventory is below threshold level  $S$ , the retailer will order to replenish inventory up to  $S+Q$  units. Otherwise, the retailer will pass. At the regular purchase price, the retailer uses the order-up-to reorder point inventory system. The reorder point is  $r$ , and the order-up-to quantity is  $R$ . The demand of the customer is price-elastic. Depending on its inventory level, the retailer may discounts its selling price to boost up demand. The decision variables are  $S$ ,  $Q$ ,  $R$ ,  $r$ , and the selling prices (regular and discount selling price). The simulation experiment covered reasonable range of values for each decision variable. Each run represented one scenario, i.e., one combination of the decision variables.

**Keywords:** demand management, price discount, multi-echelon inventory system, simulation

## 1. INTRODUCTION

Consider a three echelon (supplier, retailer, and customer) inventory system. At random times, the supplier offers the retailer a price discount. The inter-arrival time of discounts is exponentially distributed with expected value of 100 days.

For the retailer, whether or not to take the discount offer depends on its inventory level. If inventory is below threshold  $S$ , the retailer will order to replenish inventory up to  $S+Q$  units. Otherwise, the retailer will pass.

At the regular purchase price, the retailer uses the order-up-to reorder point inventory system. The reorder point is  $r$ , and the order-up-to quantity is  $R$ . The demand of the customer is price-elastic. Depending on its inventory level, the retailer discounts its selling price to boost up demand.

In this paper, we used Monte Carlo simulation to investigate the following scenarios: (1) the basic model, (2) the limited-time offer model, (3) stochastic extension of the limited-time offer model, (4) pricing to clear inventory, and (5) stochastic extension of pricing to clear inventory.

The decision variables are  $S$ ,  $Q$ ,  $R$ ,  $r$ , and the selling prices (regular and discount selling price). The simulation experiment covered reasonable range of values for these decision variables. Each run represented one scenario, i.e., one combination of the decision variables.

In the simulation analysis, the ranges of values for the decision variables were:

- $1,000 \leq S+Q \leq 7,000$
- $50 \leq R \leq 3000$

- $50 \leq S \leq 500$
- $\$7.00 \leq \text{regular selling price} \leq 10.00$
- $\$5.00 \leq \text{discount selling price} \leq 8.00$

The cost parameters used in the simulation were:

- Unit Cost (Regular)  $C_L = \$5.00/\text{unit}$
- Unit Cost (Discount)  $C_D = \$4.00/\text{unit}$
- Holding Cost/Year 15% of cost
- Ordering Cost \$50
- Backorder Cost \$10 /unit

Each combination of the decision variables was simulated for 365 days, and replicated as many times as necessary for making meaningful statistical inferences.

Descriptive statistics on the contribution margin for each scenario was generated. The contribution margin is the difference between annual revenue and annual relevant cost. The annual revenue equals daily sales in units \* selling price for the day, for 365 days. The annual relevant costs include item cost, ordering cost, holding cost, and shortage cost. The item cost is based on the weighted average unit cost.

Clearly, the weighted average unit cost is lower if the retailer orders more often at the discount price.

The results of the simulation were plotted. On each plot, a polynomial trend line was fitted based on the points on the graph.

All computations were made using Microsoft Excel on a Pentium 4 2.6 GHz computer.

## 2. THE BASIC MODEL

The assumptions for the basic model are:

- Demand rate  $d$  is deterministic, i.e.  $d = \alpha p^{-\epsilon}$ , where  $\alpha=1,000$  and  $\epsilon=3$ .

- At random times, the supplier offers the retailer a discount. The inter-arrival times of discount offers are exponentially distributed with mean = 100 days. **The discount offer is good until the retailer takes the offer.**
- The retailer offers discounts to its customers whenever the inventory level is above the threshold level  $S$ . Below  $S$  the selling price reverts to the regular price. Since there are two selling prices, there are two levels of demand rate (demand is price elastic) Each run consisted of 1,000 replications. Each 1,000 replication took less than 3 seconds. The results of the simulation are summarized in Charts 1-1 to 1-5 below:

Chart 1-1 Contribution Margin vs.  $S+Q$ Chart 1-2 Contribution Margin vs.  $R$ Chart 1-3 Contribution Margin vs.  $S$ 

Chart 1-4 Contribution Margin vs. Discount Price

Chart 1-5 Contribution Margin vs. Regular Price

The contribution margin appears to be rather flat in the vicinity of  $S+Q=6,000$ . The trend-line for the Contribution Margin vs.  $R$  chart (Chart 1-2) appears to be roller-coaster-like. However, from  $R=500$  to  $R=3,000$ , the difference in contribution is less than \$750. The trend-line in Chart 1-3 shows the contribution margin dropping very fast beyond  $S=1,000$ . The trend-lines in Charts 1-4 and 1-5 suggest a regular selling price of \$7.50 and a discount selling price of \$6.50.

### 3. LIMITED-TIME-OFFER MODEL

In the basic model, each discount offer from the supplier is valid until the retailer takes the offer. This is not common in practice. In the ensuing models, we considered the more realistic practice of "limited-time-offer." The Limited-time-offer Model retained all other assumptions in the Basic Model, except that each offer of discount is good for 5 days only.

The following charts show the results of the simulation for the Limited-time-offer model:.

Chart 2-1 Contribution Margin vs. S+Q

Chart 2-5 Contribution Margin vs. Regular Price

Chart 2-2 Contribution Margin vs. R

Chart 2-3 Contribution Margin vs. S

Chart 2-4 Contribution Margin vs. Discount Price

The trend-lines appear to be unimodal. The table below shows the summary statistics, based on the input parameters suggested by the charts above:

- Threshold Level  $S=3,000$
- Order Quantity  $R=1,500$
- Max Inventory  $S+Q=6,000$
- Nominal Price \$7.50
- Discount Price \$6.50

<i>Contribution Margin</i>	
Mean	27,583
Standard Error	63
Median	28,151
Mode	20,817
Standard Deviation	2,002
Sample Variance	4,009,841
Kurtosis	0.545
Skewness	-0.858
Range	9,375
Minimum	20,817
Maximum	30,192
Sum	27,583,363
Count	1,000
Confidence Level (95.0%)	124

#### 4. STOCHASTIC EXTENSIONS

In this model, we extended the above scenario and considered stochastic demand. During the lead-time, inventory level may drop down to zero before replenishment arrives (a shortage situation), or the level may be positive when replenishment arrives. Thus the reorder point  $r$  is another decision variable of interest. We examined two alternative probability distributions – (a) Truncated Normal (i.e., demand is non-negative) and (b) Exponential.

The trend-line charts for this scenario are very similar to the ones shown above, and will not be reproduced here.

### 5. DISCOUNT TO CLEAR EXCESSIVE INVENTORY.

Since demand is price-elastic, the retailer can clear excessive inventory by adjusting the selling price accordingly. In this model, we analyzed a scenario where the retailer tweaks its selling price periodically, based on inventory level. This model is very common among sellers of commodity items or perishable goods. For example, a bumper crop of grape leads to overproduction of wine, bringing down the price of wine in retail stores. Overproduction of oil and petroleum drives down prices. As reserves are depleted, the prices slowly rise upwards. This is also very common among grocers.

This model retained all other assumptions in Limited-time-offer model except that retailer adjusts the selling price based on beginning inventory. The % discount is selling price is  $I^{(1-\delta)}/100$ , where  $I$  = beginning inventory, and  $\delta = 0.6250$ .

The following charts show the results of the simulation for the Limited-time-offer model:

Chart 3-1 Contribution Margin vs. S+Q

Chart 3-2 Contribution Margin vs. R

Chart 3-3 Contribution Margin vs. S

Chart 3-4 Contribution Margin vs. Regular Price

The trend-lines appear to be unimodal. The table below shows the summary statistics, based on the input parameters suggested by the charts above:

- Threshold Level S 3,000
- Reorder Point r 60
- Order Quantity R 1,500
- Max Inventory' (S+Q) 7,000
- Nominal Selling Price \$8.00

<i>Contribution Margin</i>	
Mean	27,839
Standard Error	74
Median	28,094
Mode	20,389
Standard Deviation	2,352
Sample Variance	5,530,168
Kurtosis	0.835
Skewness	-0.898
Range	10,673
Minimum	20,389
Maximum	31,062
Sum	27,838,767
Count	1,000
Confidence Level (95.0%)	146

## 6. DISCOUNT TO CLEAR EXCESSIVE INVENTORY: STOCHASTIC EXTENSIONS

In this model, we extended the preceding scenario for exponentially-distributed demand. The expected demand  $d = \alpha p - \epsilon$ , where  $\alpha=1,000$  and  $\epsilon=3$ .

The trend-line charts for this scenario are very similar to the ones shown above, and will not be reproduced here.

## 7. CONCLUDING REMARKS

This paper demonstrated the application of Monte Carlo simulation to analyze the problem of supply management under inducement of price discounts. We investigated the three echelon (supplier, retailer, and customer) inventory problem under the following scenarios: (1) the basic model, (2) the limited-time offer model, (3) stochastic extension of the limited-time offer model, (4) pricing to clear inventory, and (5) stochastic extension of pricing to clear inventory.

The decision variables are  $S$ ,  $Q$ ,  $R$ ,  $r$ , and the selling prices (regular and discount selling price). The simulation experiment covered reasonable range of values for each decision variable. Each run represented one scenario, i.e., one combination of the decision variables. The results of the simulation were plotted. On each plot, a polynomial trend line was fitted based on the points on the graph.

Examining the trend-lines, we were able to identify appropriate values for the decision variables. The author is currently working on an analytical approach to determine the optimal values of these decision variables.

# Taking Advantage of E-Logistics to Strengthen the Competitive Advantage of Enterprises in China

**Jianjun Wang, Deli Yang, Qiong Guo, Yunfu Huo**

School of Management, Dalian University of Technology, Dalian, Liaoning 116024, China  
wmeagle717@sina.com

## ABSTRACT

With the fast development of the global economy, how to deliver the right products to the end-users in the demanding time and places becomes more and more important to the enterprises. In order to improve the competitive advantages, Chinese enterprises, especially the large manufacturers, need to develop e-logistics function and modern supply chain management systems. This paper describes the changing environment, such as competition, global trends, and logistics operations. Then the e-logistics is discussed, and it presents that the Descartes can improve the level of the information sharing and creates a new source of advantage to ensure competitiveness in today's dynamic manufacturing marketplace. At last some suggestions are given, including establishing an integrated network, selecting the right industries, and so on.

**Keywords:** E-logistics, supply chain, information system

## 1. INTRODUCTION

Now China has become the manufacturing powerhouse in the world. With the development of the global economy, the vast majority of goods are bound for global destinations. China produces the majority of the world's televisions, VCD, refrigerators and other goods. China's share of world trade is already in the top 10 nations and has an annual economic growth rate of almost 8% the past decade. In 2003, China accounted more for 3% of the global trades; some experts forecast it will be 10% in the 2020 (Shawn P. Daly, Lindsay X. Cui.2003).

Fueling Chinese industry is an increasing number of multi-billion dollar Chinese enterprises with manufacturing, distribution and services on the whole country or global scale. Many of these enterprises have regional manufacturing capabilities and distribution, warehousing and service facilities close to customers in the whole country, even in Japan, North America, Europe and other parts of the world.

## 2. IMPACT ON COMPETITION

Since the advent of internet technology, the computing environment in many applications has been changed drastically. The increased information requirements have facilitated an integration of logistics information systems (LIS) and supply chain information systems in many companies. The increasing use of electronic commerce and enterprise resource planning and other logistics information systems tools and techniques will shape the business process for the foreseeable future. Companies should understand their options and their impacts when making decisions to support their supply chain systems (Stephen M. Rutner.2003).

Of the four key elements to succeed in business -- product, price, promotion and place -- manufacturers nowadays are able to produce the same quality of products at the same price using the same promotions. However, they have developed a different strategy for place -- the channel of distribution to deliver goods and services from factories to end-users. But China's logistics infrastructure is straining under the weight of its new economic growth. Chinese companies have begun to realize that E-logistics is the new frontier of competition in the digital economy.

## 3. GLOBAL TRENDS AND LOCAL IMPLICATIONS

Most large-scale Chinese companies have developed strategic partnerships with global information technology leaders such as SAP, IBM, HP, Dell, Gateway, Ericsson, Motorola, NEC, and many others. As a result, Chinese companies are becoming increasingly integrated into global supply chains that must be agile, flexible and -- with the adoption of the internet -- electronically linked to ensure they are responsive to the needs of today's rapidly changing and demanding marketplace.

Accelerating this integration is the rapid adoption of various Internet technologies by global technology leaders as they work to sustain and strengthen their competitiveness in today's digital marketplace. These initiatives tend to fall into two broad categories (1) supply chain management; (2) customer relationship management

### 3.1 Supply Chain Management

To send products that customer needs to the retailer and the final customer quickly becomes the main means of the enterprise's surviving and competitive advantage.

The competition not only happens between the firms, but also happens in the different supply chain in the future. The main task of supply chain is supporting logistics from the primitive supplier, several processes of produce and transport to customer finally (Niklas Aldin.2003).

Companies large and small are launching a broad range of supply chain management initiatives designed to improve operating efficiencies, raise service levels and boost profitability. Initiatives such as B2B integration, e-procurement, collaborative planning and – more recently – e-logistics are being launched in cooperation with trading partners to increase efficiencies and drive waste out of supply chains.

### 3.2 Customer Relationship Management

Customer Relationship Management (CRM) can manage the customer's information effectively and meet their needs of production and service, in order to attract new customer, lock the frequent customer for enterprises and improve benefits and competitive advantage it develops long-term, steady and trusting relationship with the customer.

More and more firms communicate with their customer by information technology under the environment of e-business, which makes it possible to extensively collect and analyze the customer's information. It resolves the problem of customer information management, which puzzled the enterprises for a long time, it also improve the customer's service level and customer's satisfaction. It obtains and keeps the customer for the enterprise; i.e. expends and keeps the financial resource for the enterprise. So the customer relationship management has already become the important content of the organization management innovation under the e-business.

Every communication between the firm and the customer is regarded to be beneficial and value-added in the CRM, the customer's loyalty to the firm is won by mutual communication with the customer. Through correctly guiding, most customers would like to share their own information with enterprises (Nianlian Yi.2003 [6]).

CRM mainly involves such "enterprise's front desks" as market intelligence analysis, marketing and customer service etc, in order to complete it requires the positive cooperation of customer-oriented functional departments. Meanwhile, if it wanted to offer satisfactory products and service to the customer, the processes such as product design, manufacture and produce controlling etc which are regarded to be the "enterprise's backstage supporter" should be involved. The idea and practice of CRM in the e-business need the cooperation of the function department of the whole

enterprise; it also needs the adjustment and innovation to the whole enterprise's procedure.

Companies are adopting e-business to develop deep, personalized relationships with their customers (often consumers). Nearly 50% of Dell's \$32 billion in annual revenues are now transacted over the web and other manufacturers and distributors are also reporting sharp increases in on-line sales. And the U.S. is not the only country with booming e-business sales. In Japan, for example, e-business is expected to grow from \$7 billion in 2001 to \$25 billion by 2003, with approximately 40% of this from PCs and peripherals alone.

### 4. IMPACT ON LOGISTICS OPERATIONS

Both types of initiatives – supply chain management and customer relationship management – dramatically impact how China suppliers and their foreign business partners manage their global logistics operations. The initiatives highlight the need for real-time, accurate logistics information that can be shared by supply chain players to allow for more intelligent logistics decision-making and timely responses to planned and unplanned events in the supply chain.

E-business in particular is accelerating the way logistics are managed by companies across the entire value chain. The size of shipments are shrinking, shipment frequencies are increasing and the ubiquity of the internet is providing new opportunities – and challenges -- for companies serving customers who are geographically dispersed, difficult to predict and sensitive to price and service levels.

Table1 compares traditional logistics with e-logistics of today (Yaohua Song, Hanping Hou.2003).

Table1. The Difference between Traditional Logistics and E-Logistics

	Traditional Logistics	E-Logistics
Shipment Type	Bulk	Parcel
Customer	Strategic	Unknown
Customer Service	Reactive, Rigid	Responsive, Flexible
Distribution Model	Supply-driven Push	Demand-driven Pull
Inventory/ Order Flow	Unidirectional	Bidirectional
Destinations	Concentrated	Highly Dispersed
Demand	Stable Consistent	Highly Seasonal, Fragmented
Orders	Predictable	Variable

E-business has a ripple effect up the supply chain that impacts China assemblers and their suppliers as foreign buyers work to synchronize their operations with actual customer demand. Historically, supply chains have been structured to "push" products from suppliers to consumers with limited – if any – information available

about real-time consumer demand. This “push” approach typically results in supply chain distortions marked by excess inventories, obsolete products, unsatisfied consumer demand and an inability to forecast accurately.

On the other hand, “pulling” products across the supply chain helps to ensure supply and demand are synchronized by feeding information about actual - not forecasted – orders to the enterprise, suppliers and third party logistics providers. The benefits of a pull system are obvious but realizing them requires fundamentally rethinking how logistics should be managed throughout the entire order to delivery process.

Now, Chinese companies and their customers gradually begin to rely on third party logistics providers (such as freight forwarders) to coordinate the logistics and related decision-making required to ship products from main land factories to various destinations. However, due to industry fragmentation and technology limitations it has been difficult (if not impossible) to obtain accurate information on the position and status of goods as they move across the supply chain. As a result, the logistics operations of most shippers, customers and logistics providers themselves function in an extremely information poor environment despite the fact that logistics plays a critical role in their business operations: the timely and cost-effective delivery of goods to customers.

## 5. E-LOGISTICS

E-Logistics is a dynamic set of communication, computing, and collaborative technologies that transform key logistical processes to be customer centric, by sharing data, knowledge and information with the supply chain partners. E-logistics also enables synchronization of events and right decision-making. The ultimate objective is to deliver the right products in right quantities at the right place and time to the right customers.

E-Logistics leverages the power of the internet and other technologies (such as wireless) to provide robust information to supply chain participants and offer unprecedented levels of visibility across the entire supply chain. A growing number of e-logistics solution providers and service companies are tapping into this opportunity by addressing logistics issues such as supplier selection, asset utilization, pricing, inventory management, order visibility, and order fulfillment. Start-ups, software companies, and “old economy” logistics providers are bringing to market a variety of products and services that address the huge logistics inefficiencies burdening today’s supply chains.

While these companies may indeed provide value to Chinese shippers, the Descartes can provide the level of global connectivity required to create value through

networked communities. The key attractions of this networked community are (1) fewer integration points required to connect to network members; (2) an exponential increase in value for each member as more participants join the community; and (3) a common infrastructure for the communication and exchange of information. Imagine for a moment a world without a global telecommunications network where instead phone users strung a separate line to each new person they wished to speak with.

The Descartes’ Global Logistics Services Network (GLSN) provides technology to ensure consistency and integrity of communication throughout supply chain communities. It is an information platform encompassing thousands of transportation carriers, logistics intermediaries, and users of transportation services around the globe. The network securely registers, connects, and manages participants. In addition to providing a standard for inter-enterprise business connectivity, it acts as a logistics process framework for end-to-end shipping management.

The GLSN enables organizations to build high-performance supply chains, providing real-time visibility and decision support. Its open architecture allows trading partner systems to seamlessly integrate with logistics-critical data and business rules, wherever and however they reside. It enables organizations to connect with a single, simple mechanism that incorporates security, so only preauthorized users access information, applications and documents. The GLSN manages the integration of the hundreds of data communication standards, and maintains responsibility for data monitoring, quality and integrity. And recognizing that each participant may have different technological abilities and needs, it supports all common communication protocols, leveraging comprehensive embedded dictionaries for translation.

Tapping into this global network can provide Chinese shippers and their customers with visibility of orders (not just shipments) across their supply chains. Manufacturers can use the Descartes network to “link” together their manufacturing order systems with shipment tracking systems to provide a single, unified view into the status of orders as they make their way from PO to final delivery. With true order visibility, shippers, buyers, and logistics providers understand where goods and inventories reside across the supply chain and can make intelligent, proactive logistics decisions based on this information.

Beyond the obvious benefits of order visibility across the supply chain, access to accurate, real-time logistics information provided by the Descartes Network allows companies to undertake various improvement initiatives that can drive savings, increase revenues and improve their overall competitive advantage. Based on experts’ estimates and experience, companies undertaking such

initiatives can realize a 10-20% reduction in their total logistics costs, improve productivity and enhance service levels.

Logistics improvement initiatives enabled by Descartes include inventory management, shipment planning, mode selection, reverse logistics optimization, performance measurement and other efforts. In the past, such efforts have been extremely burdensome to implement due to limited logistics data. However, armed with meaningful logistics information, management can bring their logistics operations out of the dark ages and into new era. This will improve the overall responsiveness of their supply chains and create a new source of advantage to ensure competitiveness in today's dynamic high-tech manufacturing marketplace.

## 6. SUGGESTIONS

### 6.1 Establishing an Integrated Network

Looking at it from a bigger picture, the current logistics landscape is fragmented. Therefore, the key challenge is for us to ally together to establish a proper network of services to cover the whole region efficiently. It is an arduous challenge to pick out the right partners to work with in providing an end-to-end supply chain solution. Further to that, our country alone has very different customs, cargo and tax policies. Therefore, it is vital to engage local partners in order to overcome any barriers involved in clearing overseas shipments.

### 6.2 Improving the Awareness Level Of Logistics Services

The low awareness level of high-value online logistics services is a most pressing issue to deal with at present in the market. There are a lot of enterprises in China that are not fully convinced of the value of adopting IT-enabled processes in their operations let alone e-logistics services. Creating the much-needed awareness is very important in order to keep the business flowing. Actually, customers need to view e-logistics services as the means not just to lower costs and shorten time cycles but, more importantly, to enhance their competitiveness in the marketplace by concentrating on their core competencies.

### 6.3 Selecting the Right Industries

Another addressed challenge is to pick the right industries to target. Each industry has its unique culture and requirements and thus it is difficult for a service firm to cater to a wide range of industries. The firms need to focus on building up expertise in particular market segments so as to capitalize on particular market opportunities.

### 6.4 Establishing Training Mechanism

With regards to available resources, traditionally the manpower in industry is of a physical nature or manual-labor-intensive. Incorporating IT into the services requires a higher level of skills. This type of skill set is lacking at the moment. Thus, the challenge is to establish training facilities to increase the availability of skilled and qualified labor to man the IT-enabled processes.

### 6.5 Building an E-Logistics Product Portfolio

Local and foreign clients have different requirements and cultural expectations. Although the current demand stems more from foreign clients, it is important not to overlook the potential demands of locals. Hence, a key challenge is to be able to create a product portfolio that can encompass the needs of both sets of clients. Furthermore, it is already hard enough to cope with the ever-changing needs of client requirements. Turning all the customer needs into an integrated and flexible set of services is a tall enough order even for the most experienced industry players. A good way to understand the customer needs thoroughly is to embrace the customers' business challenges as one's own.

### 6.6 Improving the Technology Level

It is inevitable that companies with strong financial backing or relevant industry experience will have an upper hand in developing sophisticated technology for their clients. As such, newly established companies will find it difficult to compete with them in building a solid set of services. In this industry, credibility and reputation are valued assets to have. Research has revealed that even a simple but important technology such as bar coding is still missing in most warehouses in the whole country. The technology gap between the local and international players is also a key concern. So we should narrow the technology gap between the local and international players as soon as possible.

### 6.7 Industry, Government and the Academic Working Together

In order to take advantages of e-logistics, the industry, government and the academic should work together.

The industry should focus their effort on the following issues:

- ò Adoption
- ò Technology development
- ò Investment and integration
- ò Adoption and development of processes.

The issues that belong to the government are as follows:

- ò Awareness development
- ò Standards setting
- ò Regulatory oversight
- ò Intergovernmental relationships
- ò Infrastructural support and development.

Academia should take the following aspects into their research fields:

- ò Basic research and development
- ò Implications of technology on the environment
- ò Determining what works and what doesn't
- ò Educating and publicizing into their research fields

## 7. CONCLUSION

Today's supply chains require effective logistics management to meet the requirements of increasingly demanding global customers able to choose when, how and where they want to receive their goods. The urgency for improvement is being accelerated by the widespread adoption of internet technologies and applications such as e-business in the global market. E-logistics can improve the overall responsiveness of supply chains and create a new source of advantage to ensure competitiveness in today's enterprises.

## The Distribution Network Planning Using Geographic Information System (GIS)

Hai Yu<sup>1</sup>, Linning Cai<sup>2</sup>

<sup>1</sup>Department of Industrial Engineering, Tsinghua University, Beijing 100084, China

<sup>2</sup>Department of Industrial Engineering, Tsinghua University, Beijing 100084, China

### ABSTRACT

To improve the customer service level, tobacco companies in China use the strategy of direct delivery. But this strategy has a great influence on the local company's operation cost. In this paper, a distribution planning of the local company is made to decrease the operation cost.

The distribution planning includes the location and choice of the distributed centers and the transferring points. In this problem, the Greedy Dropping Heuristic Algorithm is used twice to decide the distributed centers and transferring points. After the transferring points are set, the Vehicle Routing of each transferring points is presented. The savings algorithm is used in this process.

To analyze the complicated data, as well as to make the decisions, GIS (Geography Information System) technology is used, which turns to be a great help.

**Key words:** logistics, distribution, inventory, vehicle routing problem

### 1. INTRODUCTION

To improve the customer service level, tobacco companies in China use the strategy of direct delivery, delivering tobacco from local company directly to their customers, i.e., different retailers. But this strategy has a great influence on the local company's operation cost, which includes the labor cost of delivery workers, the cost of delivery vehicles and the inventory cost. All the cost mentioned above adding up will be a great number. For example, for a local company studied, the delivery cost counts up to about 7 million RMB, while the inventory cost is as much as 35 million RMB. So in this paper, a distribution planning of the local company will be made to decrease the operation cost.

The project is divided into two parts; the first is to determine how many distribution centers will be used. Now in their system, there are 42 distribution centers, including 11 bigger one belonging to 11 sale divisions and 31 smaller one dispersed in different towns in convenience for the distribution of tobacco. Considering the position and scale of all the 42 distribution centers, as well as the traffic conditions, several candidate schemes consisting of different distribution centers are put forward. After the first phase work, the main nodes of the distribution network are determined.

Based on the above structure, the second one is to determine the route planning for every demand point, i.e., the basic node in the network consisting of certain number of retailers. Considering the laws and the working load of the workers, the working time of worker is set to about 6 hours. The truckload is supposed to be big enough at first. Then using some heuristics of Vehicle Routing Problem, the route planning for every

demand point is decided. According to the total demand of all the demand points in the same route, the truck load of the vehicle and which kind of vehicle to use are decided at last.

To analyze the complicated data, GIS (Geography Information System) technology was used. The correct and ample geography information is needed in the system. So the preparation of the geography information is the first and most important step. Then all the nodes of the distribution network are presented in GIS, including the attributes of the nodes. Thus we can see clearly the distributing of the customers and the traffic conditions of them. It will be a great help for the decision that how many distribution centers should be used. When the routes computed out is displayed in GIS, we can see clearly which route is unreasonable in the scheme and thus correct it.

### 2. GIS TECHNOLOGY AND ITS USE IN LOGISTICS

In the beginning of the evolution of the vehicle routing systems, routes were designed manually with the aid of paper maps that provide the locations of the customers. From the early 1980s the development of computer technology gave birth to the systems for analyzing and displaying spatially or geographically related data. In the 1990s, the rapid growth of GIS gives us the hope of good use in logistics. However the most prevalent GIS software can only deal with and display the data that is formatted. While in the real life, the dimension of the location and routing problems are quite large. To design routing more efficiently, it is necessary to develop decision support systems that incorporate effective methods and spatial techniques.

Considering the present conditions of the local company, 28 towns that have warehouse of themselves are regarded as the candidate transferring points, which are presented in figure 2. Also the Greedy Dropping Heuristic Algorithm is used to derive the optimal choice of the transferring points, while a constraint is added: When the candidate transferring point is removed and the customers belong to it are re-distributed, if there exists more than one customer whose distance to the transferring point is more than one and a half hours' traveling time, the transferring point should not be removed.

As the result 18 transferring points are selected to transfer tobacco to the customers. Then the 18 transferring points are distributed to the 3 distribution centers, which are presented in figure 3.

Figure 3 The scheme of 3 distribution centers and 18 transferring points

### 5. THE VEHICLE ROUTING OF EACH TRANSFERRING POINTS

For each transferring point, the customers belong to it should be distributed from it and in the end return to it as the depot. In the real problem, the importance of choosing proper algorithm and modifying the routing according to the actual conditions are equal. In the solution of this problem, the Savings Algorithm presented by Clarke and Wright in 1964 is used. While in this algorithm, the truckload constraint and the time constraint are considered at the same time.

Then the results of the vehicle routing are presented in the geographical information system. With the aid of the experience of the workers and the local transportation

conditions etc., the routing schemes are modified. Figure 4 presents an example of the vehicle routing of one transferring points.

Figure 4 One example of the vehicle routing

### 6. CONCLUSIONS

From the above we can see that whenever the choice and location of the distribution centers of the choice of the transferring points or the vehicle routing of each transferring problem, the GIS technology is a great help in all the decisions. From complex and dull various data to the simple and sensed view of the map, the human can take part in the decisions directly.

Finally, the distribution plan comes to be successful, which decrease the local company's operation cost by 10% or so.

## ABSTRACT

This research has developed an analytical framework based on resource-based theory. It intends to find out the impact of different attributes on supply chain performance and financial performance under different IT capabilities and application degrees. The hypothesis test model incorporating five measuring variables is conducted; they are strategy of e-business, application degree of e-business, information technology capability, supply chain performance and financial performance. The results indicate that e-business strategy will affect the application degree for either high-tech industry or traditional industry; and higher IT capability will make the application degree impact on supply chain performance more significant while financial performance is not obviously activated. E-business should be a strategic policy. The managerial full support and involvement, cautious selection of new operational strategy, as well as the integration of e-business process and information, will make IT application, e-business process and readiness collaborate closely, so as to create business value and promote operational performance of supply chain.

**Keywords:** application degree of e-business, information technology capability, supply chain performance, resource-based theory

## 1. RESEARCH BACKGROUND AND MOTIVE

Coming along with the knowledge economy, the trend of globalization, digitization unceasingly challenges existed management concepts. The development of e-business has become the primary consideration to be survived. Information technology (IT) is applied to promote operational efficiency in the past. Nowadays, due to the maturity of internet technology, it has been applied to commercial management, and to integrate the information system. The development of e-business will undoubtedly induce further revolution of supply chain (SC). The construction of business to business (B to B) can especially improve the efficiency and circulation speed of information, enhance the effective management on supply chain, and decrease the risk and pressure of stock.

The rapid change of IT speeds up the footstep of e-business and the integration of business process across different enterprises. Upstream and downstream over the supply chain system can promptly and correctly link their logistic flow, information flow and cash flow together. The efficiency and effectiveness of whole supply chain is upgraded, and the demand uncertainty is decreased. Supply chain management can therefore be greatly improved. However, whether the competence of e-business can be improved depends on its ownership of flexible information technology. Only those who own superior information capability can realize the competitive advantage in the e-environment.

The application of information system has positive influence on supply chain management in many companies (Barua *et al.*, 2001). Most of the literatures focused on the theoretical study, and little of them

discussed in empirical way. This paper will measure the IT capability of enterprise by using resource-based theory. The impact of e-business on supply chain performance and financial performance will be analyzed under different IT levels and corporate features, in order to make concrete conclusion and suggestion. If the enterprise can integrate the inner and outer management information system while constructing e-business, the supply chain performance and competitive strength can be greatly improved.

The major objective of this paper is to investigate the impact of e-business on supply chain performance and financial performance for manufacturers under different IT levels and corporations.

## 2. EB STRATEGY AND IT CAPABILITY

### 2.1 E-business and Strategy

E-business is the generic name of business models and processes accomplished by internet technology, it focuses on the improvement of long term business performance (Simchi-Levi *et al.*, 2000). E-commerce corresponds to the ability to operate business in electronic way. So e-commerce is only one part of e-business; internet is the driving force of corporate re-engineering. E-business emphasizes more on the development of extended business, that is, business interior, business to customer (B to C) as well as business to business (B to B) transactions.

The applications of e-business onto supply chain have many different configurations. Lee *et al.* (2002) divided e-business applications into e-commerce, e-procurement and e-collaboration.

- (1) E-commerce: Assisting the supply chain partners inside the network system can quickly confirm or feedback via internet to fulfill customer's requirement.
- (2) E-procurement: Corporations can access direct or indirect materials, handle value-added services such as transportation, warehousing, payment mechanism, quality assurance and documentation management etc. via on-line mechanism.
- (3) E-collaboration: Accelerate the coordination and cooperation of various transaction activities among the supply chain partners including all suppliers and customers exploiting the internet.

Johnson *et al.* (2002) defined e-business as the marriage between the integration of internet and supply chain. This marriage transformed many processes within the supply chain from procurement to customer management and product design. The enterprise must integrate the information system with their developed e-business capability. The effective integration can systematically utilize all resources and take advantage of leverage function. Grandon and Pearson (2003) identified three factors to be influential concerned with the perception of strategic value in other information technologies: operational support, managerial productivity, and strategic decision aid.

Barua *et al.* (2001) suggested a e-business value model which included e-business drivers, operational excellence measures and financial measures as measuring indexes. E-business drivers encompassed three areas: e-business processes for customers and suppliers; IT applications for customers, suppliers and internal operations (all of them must be integrated); and the e-business readiness of customers and suppliers. They stated that in trying to bring about e-business transformation, companies generally focused too much of their attention on technology. But systems didn't work in a vacuum, and senior managers must recognize the complementary nature of technology, business processes and e-business readiness throughout the value chain.

## 2.2 IT capability

Mata *et al.* (1995) stated that managerial IT skills were rare and firm-specific which might be the source of sustained competitive advantage. The resource-based view assumed firms possessed four kinds of resources that differentiated it from other firms; that is, value, rareness, imperfect imitability and insubstitutability (Barney, 1991). The dynamic capabilities were defined as the firm's ability to integrate, build and reconfigure internal and external competences to create profit and achieve competitive strength (Teece, Rumelt, Dosi and Winter, 1994; Teece, Pisano and Shuen, 1997).

Broadbent and Weill (1997) suggested IT infrastructure should include technical IT infrastructure and human IT infrastructure. Broadbent, Weill and St. Clair (1999)

pointed out the organization should be equipped with physical IT infrastructure such as hardware, software, communication technology, data base, application etc., as well as human IT infrastructure such as technique, experience, ability and knowledge etc. Via the combination of technology and human, the shared IT service can be constructed to provide services, such as networking, data access and exchange, business process support etc., to decrease operational cost and improve the performance and competence of organization.

Byrd & Turner (2000) summarized IT capabilities into eight dimensions, they are IT connectivity, applications functionality, IT compatibility, data transparency, technology management, business knowledge, management knowledge and technical knowledge.

As for the supply chain performance, Frohlich (2002) indicated that operational performance was based on faster delivery times, reduced transaction costs, and enhanced inventory turnover related to web-based integration. Operational excellence measures included the percentage of online business, the percentage of online procurement, the percentage of online customer-service provided online and order delivery time. Financial measures included revenue per employee, gross profit margin and return on assets.

## 3. DESIGN QUESTIONNAIRE SURVEY

### 3.1 Survey Structure

The structure of this survey includes five factors as illustrated in Figure 1. IT capability and corporate feature are treated as moderating variables in order to study whether they will affect the relationship between e-business and SC performance. The relationship between hypotheses and various variables will be validated empirically in this paper.

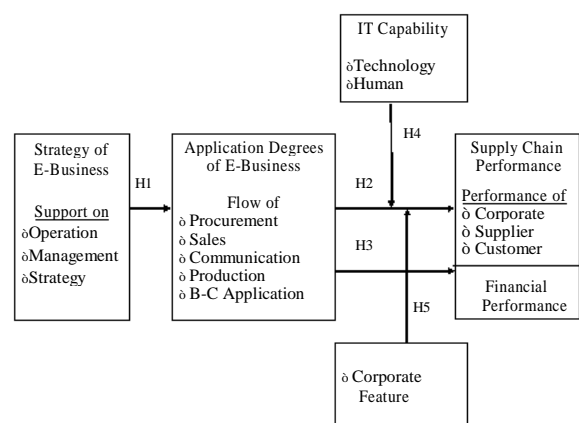

Figure 1 Research structure

Synthesizing the relevant literatures, we generate five hypotheses:

H1: Application degree of e-business is positively related to strategy (goal) of e-business.

H2: Supply chain performance is positively related to application degree of e-business.

H2a: Operational performance is positively related to application degree of e-business.

H2b: Supplier performance is positively related to application degree of e-business.

H2c: Customer (buyer) performance is positively related to application degree of e-business.

H3: Financial performance is positively related to application degree of e-business.

H3a: Gross profit margin is positively related to application degree of e-business.

H3b: Net profit margin is positively related to application degree of e-business.

H4: The impact of application degree of e-business on supply chain performance is significant dependent on IT capability.

H4a: The impact of application degree of e-business on operational performance is significant dependent on IT capability.

H4b: The impact of application degree of e-business on supplier performance is significant dependent on IT capability.

H4c: The impact of application degree of e-business on customer (buyer) performance is significant dependent on IT capability.

H5: The impact of application degree of e-business on supply chain performance is significant dependent on corporate feature.

H5a: The impact of application degree of e-business on supply chain performance is significant dependent on the industrial type.

H5b: The impact of application degree of e-business on supply chain performance is significant dependent on organization scale.

### 3.2 Questionnaire Design

There are five factors considered in our survey sheet, they are strategy of e-business, degree of e-business, information technology capability, supply chain performance, financial performance. Five factors contained in each characteristic are three, five, seven, twelve (4, 4, 4) and two items in respective. Survey data is measured in ordinal scale (1, 2, 3 ...) according to Likert's five grading scales (e.g. 1 represents "contribute no benefit", 5 represents "contribute full benefit"). The financial performance is mainly obtained from TEJ data base.

## 4. RESULT ANALYSIS AND DISCUSSION

### 4.1 Data Collection

The investigation survey sheet is designed originally on literature review and revised through experts interview, so that the contents effectiveness can be well assured. The survey population comes from Taiwan Top 1000 Manufactures, as well as the corporate joined AB E-Business Program (An e-business promotion program focusing on procurement and customer order processing that is supported by Taiwan, China). Survey data is randomly sampled and collected through e-mail and paper-mail, we issue 830 samples and 105 effective sheets (12.72%) are collected.

The received 105 effective investigation sheets covered different corporate features, with which can be used for analysis in effectiveness. The statistical software tool SPSS for Windows 10.0 is used for corresponding data analysis, it is also applied for variables validity and reliability assured.

Confidence analysis assures the consistency and stability of the measuring result. Confidence analysis takes the functionality to measure the degrees of data confidence within each factor and its related attributes; if the confidence Cronbach  $\alpha$  value is greater than 0.7 then the investigated data is assumed to be sufficient confidence. In general, the Cronbach  $\alpha$  value for each factor is greater than 0.8.

### 4.2 Declarative Statistics

The surveyed manufacturers are categorized into three groups (high-tech co. x 52; traditional co. x 43; foreign co. x 11). Declarative data analysis is applied based on 5 factors and its related attributes in correspondence to three groups of corporate organization, with which it can show the difference among them (Table 1).

In general, the foreign corporations (all of them are electronics industry) invest more in e-business and IT than local industries do. The strategies of e-business are mostly for the purpose of operational support. It implies most of the enterprises perceive e-business as the tool for customer service improvement, distribution channel development and competitiveness enhancement. The application degrees of e-business on procurement and sales flow are lower, because they involve not only the enterprise itself, but also the integration with upstream and downstream enterprises. The implementation is more difficult than other items that make their application degrees the lowest. Currently, the application of e-business is mainly focused on internal communication flow, such as using e-mail to transmit information. The IT capability of foreign electronic corporations is better than that of local high-tech corporations, while the later surpasses that of local traditional industries. As for the performance, information sharing and management perform better.

Table 1 The comparison among strategy, application degree, IT capability and SC performance

Main-factor	Sub-factor	High-tech industry	Traditional industry	Foreign corporation
Strategy	Operational support	4.109	4.092	4.364
	Managerial productivity	4.020	4.006	4.409
	Strategic decision support	3.993	3.983	4.242
Application degree	Procurement flow	2.439	2.607	3.299
	Sales flow	2.554	2.589	3.082
	Internal communication flow support	3.758	3.513	4.136
	Production process	3.119	2.875	4.068
	Business process of B to C	3.177	3.258	3.879
IT Capability	IT connectivity	3.621	3.613	4.136
	Application functionality	3.454	3.425	4.227
	IT compatibility	3.566	3.500	4.046
	Data transparency	3.347	3.331	3.750
	Business operation knowledge	3.648	3.575	3.925
	Management related knowledge	3.517	3.508	3.667
	Professional IT knowledge	3.862	3.546	3.950
Corporate operational performance	Order fulfillment management	3.728	3.872	4.000
	Information flow management	3.898	3.910	4.350
	Procurement management	3.687	3.932	4.000
	Inventory management	3.602	3.667	3.700
Supplier performance	Intensify information sharing	3.510	3.795	4.000
	Shorten delivery lead time	3.388	3.718	3.800
	Increase delivery reliability and service level	3.347	3.590	3.800
	Decrease delivery cost of supplier	3.204	3.590	3.400
Customer (buyer) performance	Intensify information sharing	3.551	3.641	3.700
	Improve customer service level	3.571	3.692	4.000
	Increase customer satisfaction	3.571	3.692	3.800
	Upgrade customer royalty	3.347	3.615	3.600

### 4.3 Correlation Analysis

Pearson analysis is used to review whether the paired comparative data is significant difference, eight attributes are considered in Pearson analysis. Parts of the results can be summarized as below.

- (1) Strategy and application degree of e-business have positive correlation ( $r=0.461$ ;  $p \leq 0.01$ ).
- (2) IT application degree and supply chain performance (corporate operational performance, supplier performance and buyer performance) have positive correlation ( $r=0.538$ ).
- (3) IT capability and supply chain performance has positive correlation ( $r=0.578$ ;  $p \leq 0.001$ ).
- (4) Application degree and financial performance has no significant correlation.

### 4.4 Regression Model Analysis

- (1) The relationship among strategy, application degree and supply chain performance  
The regression model is used further to validate the hypotheses and clarify their linear casual relationships. Table 2 shows that the strategy will affect the application degree of e-business, that is, the more the

enterprise learn what benefit e-business will bring for them, the eager they will construct the operation management model of e-business. Hypothesis 1 is therefore supported by this result. The higher application degree will induce higher supply chain performance that supports Hypothesis 2. Based on the correlation analysis and regression model, the application degree and financial performance has no significant relationship, that is, Hypothesis 3 is invalid. The construction of e-environment and introduction of IT require enormous investment. Successful implementation of e-business also needs the integrated support coming from technology, process and human. The operational performance can be improved in short term, but the financial performance needs long term efforts and the integration of systems.

- (2) The impact of application degree on supply chain performance under different IT capabilities  
Based on Hypothesis 4: IT capability will affect the relationship between application degree and supply chain performance, we sort surveyed corporations into two groups (higher IT capability and lower IT capability) to analyze the impact of application degree on supply chain performance. Hypothesis 4 is supported based on the analysis of Table 3.

Table 2 The regression model among strategy, application degree and supply chain performance

Dependant variable	Prediction variable	R <sup>2</sup>	$\beta$	t value	p value	Hypothesis
Application degree	Strategy	0.212	0.461	5.142	0.000***	H1
Order fulfillment management	Application degree	0.260	0.510	5.803	0.000***	H2a-1
Information flow management	Application degree	0.189	0.435	4.729	0.000***	H2a-2
Procurement management	Application degree	0.206	0.454	4.990	0.000***	H2a-3
Inventory management	Application degree	0.174	0.417	4.501	0.000***	H2a-4
Supplier performance	Application degree	0.359	0.599	7.328	0.000***	H2b
Customer (buyer) performance	Application degree	0.332	0.576	6.906	0.000***	H2c
Gross profit margin	Application degree	0.003	0.055	0.394	0.695	H3a
Net profit margin	Application degree	0.035	0.188	1.350	0.183	H3b

Remark: \*\*\* Significant level  $p < 0.001$ , \*\* Significant level  $p < 0.01$ , \* Significant level  $p < 0.05$

Table 3 The regression model between supply chain performance and application degree under different IT capability

Dependant variable	IT capability	Prediction variable	R <sup>2</sup>	$\beta$	t value	p value
Operational performance	High	Application degree	0.107	0.327	2.423	0.019*
	Low		0.095	0.308	2.173	0.035*
Supplier performance	High	Application degree	0.274	0.523	4.297	0.000***
	Low		0.162	0.403	2.954	0.005**
Buyer performance	High	Application degree	0.323	0.568	4.836	0.000***
	Low		0.109	0.330	2.341	0.024*

Remark: \*\*\* Significant level  $p < 0.001$ , \*\* Significant level  $p < 0.01$ , \* Significant level  $p < 0.05$

(3) The impact of application degree on supply chain performance under different corporate features

Hypothesis 5a proposes that the industrial type will affect the impact of application degree on supply chain performance. Based on the linear regression model, we observe that application degree has significant impact on supply chain performance, and IT capability will affect the supply chain performance no matter what industry group the corporation is belonging to. This means that H5a is not accepted.

Hypothesis 5b suggests that the organization scale will affect the impact of application degree on supply chain performance. The organization scale is divided into two groups based on the employee population – 1 stands for the population is greater than the mean value while 2 smaller than it. The result shows that application degree has significant correlation with supply chain performance in both groups, which means H5b is not accepted too.

#### 4.5 Discussion

The validation of the hypotheses proves that all hypotheses are true except H3 (the financial performance and application degrees of e-business have no significant correlation.) and H5 (the impact of application degree of e-business on supply chain performance is not significant dependent on corporate feature.)

### 5. CONCLUSION

This paper investigates the relationship among strategy of e-business, application degree of e-business, IT capability, corporate feature, supply chain performance and financial performance. The results obtained from the analysis can be summarized as below:

(1) Application degree of e-business is positively related to strategy of e-business.

There is no doubt that implementation of E-Business will increase the competitiveness, save the cost and reduce the risk. However, the implementation of E-Business involves the strategic consideration of the business process. Top management must clearly figure out its process re-engineering project, set unique operation model and definite target for whole supply chain system, so that the competitive model of e-business can be constructed.

(2) Supply performance is positively related to application degree of e-business.

The higher application degree of e-business will bring about better supply chain performance. E-business is becoming the key success factor of competitive strength in the global environment. The brand new operation model created by e-business can shorten the unforeseen distance with partner, and control the stock status of upstream and downstream firms whenever it is necessary. The immediate, flexible and speedy operation ability earns the competitive strength for enterprise in the global fast changing environment.

(3) Financial performance is not significantly related to application degree of e-business.

The promotion of e-business should be sustained to improve the operational performance of business, until then, the profit margin can be increased further. Besides, the introduction of e-business and related information system require vast investment. Only long term continuous implementation of e-business can actually improve the financial performance.

(4) The impact of application degree on supply chain performance is significantly dependent on IT capability level.

E-business is the utmost application of IT. While applying e-business to business model and flow, a company must integrate it with its information system. Only the successful integration can make all resources emerge their multiplicative effect.

(5) The impact of application degree of e-business on supply chain performance is significantly dependent on industrial type.

A company should be capable to adapt itself to the dynamic fast changing environment. In general, the high-tech industry has capital-intensive and flexible information system, so the implementation of e-business is easier than traditional industry. But the encouragement from government has also made many large-scale traditional industries introduce e-business to improve their supply chain performance.

Most information industry in Taiwan is OEM or ODM factory. The short life time of product, the dispersion of suppliers, the fierce competition in the market as well as many uncertain factors might disturb the supply chain performance while promoting e-business. The market uncertainty in tradition industry is much less than high-tech industry, so the successful implementation of e-business will greatly improve its supply chain performance.

(6) The impact of application degree of e-business on supply chain performance is significantly dependent on organization scale.

E-business implementation is long-term strategic change, hence, the acceptance coming from employees plays an important role in the change of process. Top management must be well aware of e-business implementation and steer the process change with suitable promotion methods based on employees' traits. The operational efficiency of business process can therefore be improved.

## ABSTRACT

Due to globalization and the advancement of technology, the differences are lessened among businesses in terms of IT capabilities and product quality. Operation cost has become a critical key factor of success that determines company's profit level, as well as its competence in the market. Under the environment of electronic-commerce, logistics in the supply chain ensures a stable supply of stocks to satisfy customer's demands. An efficient supply chain requires a sound inventory system and operates in coordination with well designed shipping processes. Present shipping process uses barcode in tracking the flow of materials; however, scanning barcode one at a time is tedious and inefficient. Recently, RFID has been regarded as an important technology that influences the growth of global industries in the near future. RFID is able to effectively reduce the overall cost of logistics. However, application of RFID on supply chain management is still at its infant stage. Therefore, this research attempts to develop a prototype of a Smart Logistics Tracking System (SLTS) utilizing RFID. The proposed system aims to replace barcode with RFID, eradicate the time-consuming scanning procedure and ensures an efficient flow of materials. SLTS provides a cargo tracking platform that reports real-time location of the cargo and its flow.

**Keywords:** Radio Frequency Identification (RFID), Supply Chain Management (SCM), Electronic product code (EPC )

## 1. INTRODUCTION

With the ever greater computation power and affordable network communication, businesses incorporate Internet to automate order processing, purchasing, manufacturing, shipping, marketing, and various services through uniformed information exchange under predefined policies. Industry standard allows businesses to collaborate with up-and-down-stream partners. Supply-chain collaboration improves manufacturing efficiency, reduces holding and distribution cost, shortens time to respond to market change and enhances industry's competency as well as its viability. However, the development of logistics-associated technology is laggard compares to that of the information exchange. Present shipping process uses barcode in tracking the flow of materials; however, scanning barcode one at a time is tedious and inefficient. During the second US-Iraq War, US military teamed up SAVI Technology in building a real-time RFID logistics tracking system for military cargo. The use of RFID technology allows multiple ID scanning which accelerates the speed of material flow. Scholars and industries are now under research of making RFID an affordable technology for commercial use. The success of this attempt is promised to bring about a revolutionary progress in logistics and resolves various common inefficiency problems stemmed from bullwhip effect in supply-chain. In short, by utilizing RFID, businesses are able to deliver material efficiently and maintain a low holding cost. Majority of the present cargo transportation undergoes rather slow processes due to the use of barcode which hinders the speed of material flow. With RFID, the overall performance of supply-chain can be improved significantly. However, application of RFID on supply

chain management is still at its infant stage. Therefore, this research attempts to develop a prototype of a Smart Logistics Tracking System (SLTS) utilizing RFID. With SLTS, every unit of product is attached with an EPC (Electronic Product Code) tag before leaving the factory. From that point on, each handler of the down stream supply-chain (including those involved in the processes from factory to warehouse and warehouse to retailers until products are placed on the shelf) tracks the flow of goods by scanning RFID. In short, the proposed system is able to make distribution smoother the by integrating logistics information of the up-and-down-stream businesses.

## 2. LITERATURE REVIEW

### 2.1 Supply Chain Management (SCM)

According to Ccecil Bozarth[1], SCM is the active management of supply chain activities to maximize customer value and achieve a sustainable competitive advantage. It is a discipline that devotes in developing and running supply chains in the most effective and efficient ways possible. As shown in figure 1, supply chain activities cover everything from product development, sourcing, production, and logistics, as well as the information systems needed to coordinate these activities. There are four objectives of SCM[5]:

- 1 Consumer: SCM benefits the consumers by maintaining a stable supply of goods to keep the price low.
- 1 Distribution Center: SCM serves regional market, integrates all end points and handles mass distribution operation. Distribution center utilizes computer-aided equipments in processing

customer orders, managing inventory, shipping, controlling cost and etc.

- 1 Manufacturer: SCM enables quicker respond to demands and market changes. It offers flexible production plans, quality management and various logistics support. Overall, SCM enhances order processing.
- 1 Supplier: SCM cuts down inventory which leads to reduced storage cost. SCM prevents stocking unsoldable goods due to bullwhip effect or unexpected market change.

Figure 1. Supply Chain [6]

## 2.2 Current Supply Chain

The fundamental structure of present business organization is divided into departments including production, manufacturing, marketing, human resource, accounting and finance. The objective of all businesses are pursuing is to generate profits by selling products. Increasing incomes while reducing costs is the basic concept of survival.

Under current logistics system, factory delivers products to up-and-down-stream partners through supply chain within which routine inventory checks are applied at each stage. Businesses track goods by scanning the barcode attached on each unit using infra red reader. However, this process is rather inefficient because the items can only be scanned one at a time.

Therefore, this research attempts to develop a prototype of a Smart Logistics Tracking System (SLTS) utilizing RFID. The proposed system aims to replace barcode with RFID, eradicate the time-consuming scanning procedure and ensures an efficient flow of materials. SLTS provides a cargo tracking platform that reports real-time location of the cargo and its flow.

### 2.3 Radio Frequency Identification (RFID)

RFID is an identity management technique that utilized radio frequency (RF) to transfer and intercept identity information. RFID couples radio frequency identification technology with highly miniaturized computers that enable products to be identified and tracked at any point along the supply chain [2]. The system could be applied to almost any physical item, from ballpoint pens to toothpaste, which would carry their own unique information in the form of an embedded chip [3]. The chip sends out an identification signal allowing it to communicate with reader devices and other products embedded with similar chips [4].

Figure 2. RFID structure [17]

A typical RFID structure (Fig 2) contains two major components: RFID tags and a reader. RFID Tag (transponder) contains antenna and memory. The antenna receives and responds queries from RFID reader, while memory stores ID information. There are two types of RFID tag: passive and active. Majority of RFID tags in existence are passive which converts RF energy into electrical power to generate respond signal. On the other hand, active tags require external power from embedded battery to generate initial signal.

RFID reader (interrogator) is consisted of antenna, signal processing module and control circuits. When object identification is required, reader issues query signal. Those tags within communication range receive the query will automatically respond with its ID. The reader intercepts the respond signals and retrieves the IDs that identify the items, their locations or statuses.

Currently, the concept of RFID still requires an integrated and systematic mechanism, including data content and technical / software standards. In comparison with other identification technologies, RFID has the following advantages:

- 1 Faster data retrieval
- 1 Multiple tag read/write access
- 1 It is wireless (long read range)
- 1 No line-of-sight requirement
- 1 It is resistant to harsh condition
- 1 It is reusable (reduce cost)
- 1 RF is capable of penetrating paper, wood, plastic or other non-metal materials

Table 1. comparison between various systems

	bar code	optical	vocal	finger print	smart card	RFID
storage density	low	low	high	high	very high	very high
	limited	easy	easy	hard	not possible	not possible
cost	low	mid	high	high	low	mid
access speed	slow	slow	very slow	very slow	slow	very fast
max access range	0-50 cm	<1 cm	0-50 cm	direct	direct	0-500 Cm

Table 1 shows the comparison between various identification systems. RFID stores data digitally hence is able to store more information. Also, RFID is securer

- 1 Savant is the basic working platform of Auto-ID System.
- 1 It handles large amount of data.
- 1 It provides flexible data filtering and monitoring.
- 1 It controls the readers.
- 1 It provides interface between readers and application software or ERP.

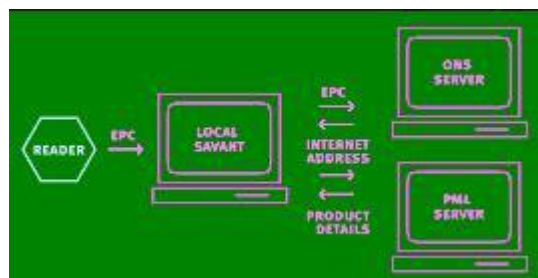

Figure 5. Savant Platform [21]

### 3. SYSTEM ARCHITECTURE AND DESIGN

#### 3.1 System Framework

This research attempts to develop a “Smart Logistics Tracking System”(SLTS) utilizing RFID. SLTS consists of two major components: Logistics Tracking Center (LTC) and on-board Positioning and Tracking Module (PTM). LTC consists of ONS server and Savant; it is the central management panel that allows manager to monitor the material flow. PTM is a mobile tracking system that reports current shipping status to LTC. Under proposed system, the traditional bar code scanning procedure is replaced with RFID technology which allows remote access of multiple data and has no line-of-sight requirement. Figure 6 shows the system framework and flow. Whenever item checking is required, RFID reader obtains IDs from tags, within its read range, then stores data to backend database. SLTS reduces resources and time required in the process.

As for logistics tracking, SLTS incorporates GPS (Global Positioning System) and GPRS (General Packet Radio Service) to achieve mobility and flexibility. GPS provides current location of the shipping items while GPRS serves as a communication channel for transmitting data. The mobile nature of SLTS enables flexible management and immediate response to changes; such capabilities are what barcode failed to provide.

Figure 6. System Framework and Flow

Goods manufactured were attached with tags and stored in the warehouse. Before shipping, RFID reader examines the items delivered and updates the associated records in the database (step 1). If item tracking is requested while shipping, the GPS and RFID reader will report its current position and item information through GPRS to Logistics Tracking Center (LTC) (step 2). Upon arriving the supplier, the items were checked using RFID reader and database is updated accordingly (step 3). When shipping out the items, supplier uses RFID reader to perform item check and updates item information to database (step 4). Finally, as customer receives the products, RFID reader checks the item and the receipt will be confirmed with LTC through GPRS (step 5). Similarly, when receiving the items, retailer uses RFID to perform item check while confirming with LTC through GPRS. The items are then placed on the RFID-enabled smart shelves (step 6).

#### 3.2 Logistics Tracking and Positioning

The most prominent feature about SLTS is its ability of tracking and positioning. Figure 7 illustrates a sample instance of material tracking in the LTC. SLTS provides interface to adjust the zooming scale, allowing managers to remotely inspect the shipping items along with neighboring street details. The map on the left shows each destination with a transaction ID (TID). With TID the items to be delivered can be referenced.

Figure 7. Real-time tracking

Figure 8 shows the on-board positioning and tracking module (PTM), which consists of GPRS adapter, GPS

receiver and embedded micro processor. The processor is responsible of coordinating GPRS, GPS and RFID reader, as well as gathering information to be transferred back to the LTC.

Figure 8. On-board Positioning and Tracking Module (PTM)

When item tracking is requested, LTC sends the query through GPRS to the target truck that loads the items (step 1). As soon as PTM receives the request, the micro processor commands GPS to reports it current position (step 2); at the same time, RFID reader scans the tags to obtain EPCs (step 3) for processor to verify the items being queried. The tracking result will be composed by processor and transferred through GPRS adaptor (step 4). Finally, LTC is able to reference more information by searching ONS based on the retrieved EPCs (step 5).

## 4. SYSTEM DEMONSTRATION

#### 4.1 Logistics Tracking Center

Figure 9 shows the LTC's main system interface. The proposed LTC utilized MapExtreme to display the geographical information and maps out the current track locations. Section A displays messages to inform user about the system's current status. Section B is the event list containing records that describe events reported by the monitor tracks. Each record is composed of several fields: event sequence, event name, event type, description and time.

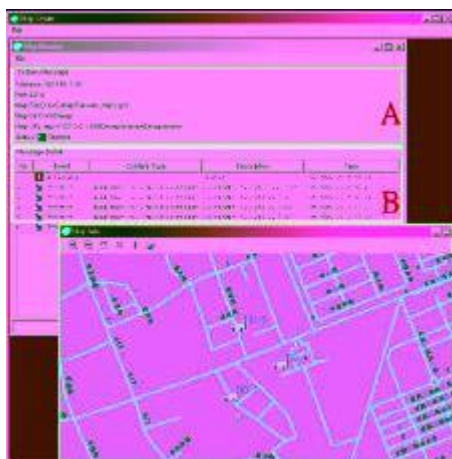

Figure 9. LTC main interface

## 4.2 Positioning and Tracking Module

Figure 10 shows the main interface of PTM which is implemented on a PDA running embedded Linux. Section A displays system status while section B keeps a list of even records indicating event, description and time occurred. PTM takes the coordination reported by GPS and send the information as in MMS format through GPRS back to the LTC.

Figure 10. Positioning and Tracking Module

## 5. CONCLUSION

A sound logistics system can improve businesses' flexibility and performance while reducing overall cost of shipping and storage. Business should incorporate information technologies into supply chain to achieve efficient data exchange and information sharing and effectively integrate up-and-down stream partners. The proposed SLTS is a system that utilizes RFID to improve the efficiency of the traditional supply chain. With the assistance of real-time monitoring facility, managers are able to keep track of material. However, further improvement should consider providing on-line shipment modification to offer greater flexibility to respond to the market change.

# The Operating Cost in a Tele-working Organization

Xiaojun Li, Pengzhu Zhang, Fanghsin Liu

Aetna School of Management, Shanghai Jiaotong University, Shanghai 200052, China  
{xi\_anlxj, pzzhang, fanghsinliu}@sjtu.edu.cn

## ABSTRACT

In this paper, we develop a model of the operating cost in a teleworking organization and describe the components and the changes of the operating costs. Then we give the application of the model for the decision-making in an organization willing to adopt teleworking.

**Keywords:** Teleworking; Operating costs; Net present value (NPV) criterion

## 1. INTRODUCTION

Telework, considered as an innovative work organization form, has emerged thirty years ago. However, at present telework has been adopted by more and more companies as a tool to cut costs, attract and retain top personnel in fields with short labor supplies[1]. Until 2003, 19.8 million persons usually did work at home as part of their primary job according to the Bureau of Labor Statistics of the U.S. Department of Labor report[2]. In Britain, official government statistics show telework has doubled in the six years since its measurement was incorporated into the Labour Force Survey. Whilst growth in some years has hit as much as 20 per cent, for 2003 it has been a more average of around 12 per cent. The total has grown from 1.01 million in 1997 to 2.113 million people or just over 7.5% of the workforce.[3]. In China, the government and companies' appeal to telework is also becoming stronger and stronger.

However, the cost is one of the key factors when an organization decides whether to adopt teleworking. The past study about the cost of telework is integrated with the cost components less and uncompletely. For instance, just as the author (On Cost In Teleworking) pointed out, the model didn't consider learning costs explicitly. Moreover, the existing studies about costs in a teleworking organization mostly are passive studies.

In this paper, our major interest is to understand the components and changes in costs when an organization changes from traditional form to teleworking form. The objective is to provide a decision support tool about the operating costs in a teleworking organization.

## 2. TYPES OF TELEWORK

Telework is defined simply as employees who work anywhere except the main office and make use of the electronic connections, for example telephone lines, cellular, wireless circuits, internet access. Telework has developed various kinds of types in different countries and locations until now, including mobile working, home-based teleworking, satellite offices, and

neighborhood work centers [1].

And it is culture to mainly influence on various kinds of types of works producing. In America, the freedom and independence is regarded as the most important factors in American literature so home-based teleworking are satisfied with the general American life. But, in Europe quantity of the staffs who spend their working time at home are less than in America.

## 3. ORGANAZATION OPERATING

If a company intends to adopt telework for the improvement of productivity, efficiency and flexibility or any else, the first one what need to do is to ascertain the new culture and than implementation completely. During the implementation, some objectors become the producer of obstacles for reformation but they will follow the majority's opinions and join the party by more and more staffs supporting the reformation. So to select a suitable pilot project is vital for an organization that has the will to adopt teleworking.

A good pilot project should have 5 elements including people, business, time, scope, and thing as the following:

- People (staffs): enthusiastic participants (volunteers) but few
- Expected reaction: criticizing the business moderately
- Business: constructing the new reasonable standard.
- Time: a period of less than one year
- Scope: suitable work scope
- Thing: a nominal cost

When the majority in the organization accepts the new company's operation that leads to the new company culture, it is time to decide which parts of works are suitable for teleworking. The following traits should provide the possible criterions for selecting the suitable department to perform the teleworking .

- Activities requiring concentration intensely and creative thought

- Individual or small-scope review and analysis
- Work that requires low levels of physical collaboration
- High telephone and computer use

However we can think over the problem from another aspect. In every organization, a variety of tasks have to be carried out by employees. In a given situation the employees of the company have a number of tasks. Each

of these tasks can be described by a number of variables or dimensions[5]. Examples of such dimensions are listed in Table 1 (On Cost In Teleworking, p56).

In fact, we can try to identify these characteristics of a task to decide whether it is suitable for teleworking. A task having the left characteristics is more suitable than the others in the table 1.

Table 1. Examples of task dimension

Degree of routinization	High	<.....>	Low
Degree of structuredness	High	<.....>	Low
Degree of active action necessary	Low	<.....>	High
Complexity	Low	<.....>	High
Need for internal communication	Small	<.....>	Large
Need for external communication	Small	<.....>	Large
Demand for competence	Small	<.....>	Large
Coordination need	Small	<.....>	Large
Time demands	Small	<.....>	Large
Environment	Stable	<.....>	Dynamic
Demand on accessibility	Low	<.....>	High

#### 4. THE MODEL OF OPERATING COST

In an organization, some of the company's costs vary with output, while others remain unchanged as long as the company is producing any output at all. Moreover, when the variable costs increases continually until it almost equals to the fixed costs, the leader in the company begins to think over another model to decrease the variable costs or change it into the fixed costs such as building up the new location or buying new equipments. With different parts of the cost, we apply the different analysis methodology. We therefore divide total cost (TC) –the total economic cost of production—into two components:

Fixed cost (FC): A cost that does not vary with the

level of output.

Variable cost (VC): A cost that varies as output varies.

Then FC can be divided assets costs, management costs and information costs. VC is composed of marketing costs, traveling costs, training costs, production costs, and other costs. The costs considered are shown in Fig 1.

##### 4.1 Fixed costs

When an organization changes from one form to another with a given work, the fixed cost will vary. To begin with the discussion, we subdivide the fixed cost into three types of costs:

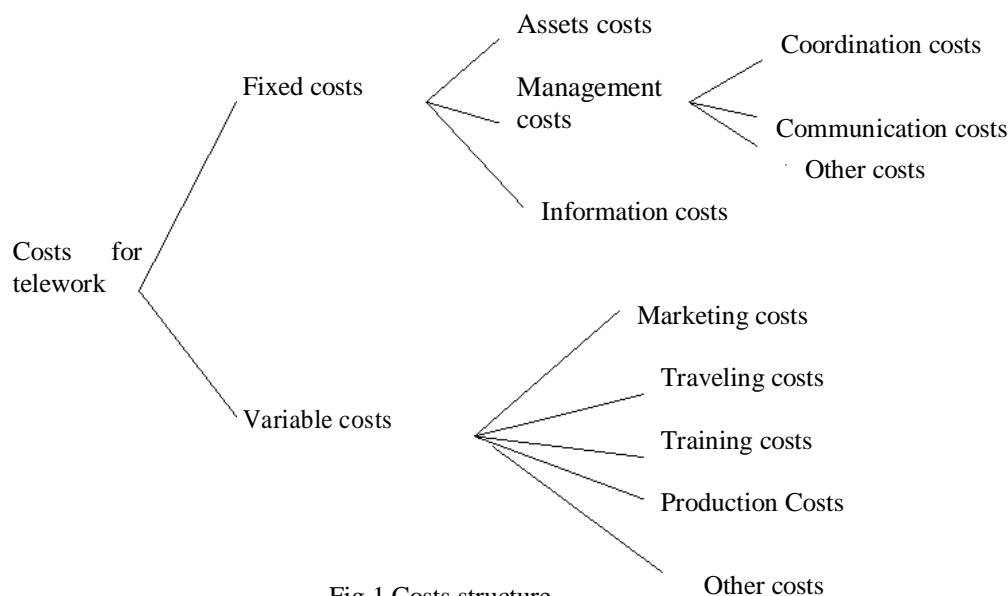

Fig 1 Costs structure

1. assets costs
2. management costs.
3. information costs

#### 4.1.1 Assets costs

We refer to assets as the combination of working equipments and space.

Teleworker must establish “electronic connectivity” to the main office. Electronic information is typically conveyed in the form of voice, page, FAX, email or collaboration software application data. It can travel over a telephone line, cellular phone circuit, cable connection, or satellite link. Once the implementation mechanism for secure electronic connectivity is established, appropriate software packages should be procured to help mitigate the problems arising from reduced face-to-face communications. Applications could include uniform messaging (i.e., email, voice mail, and FAX all delivered to and sent from a web-accessible email address), voice-over-IP (i.e., internet telephony), teleconferencing, video conferencing, threaded discussion list management, workflow management, virtual whiteboards for concurrent document review and update, and document management (publish, check-in, check-out, version control). Organizations usually choose to standardize two mechanisms, in order to keep their information secure and their Information systems burden manageable:

1. The teleworker’s computing system capability and software application suite
2. The nature of the electronic connection, including telecommunications equipment

Once standards have been established, companies must select the degree to which they will underwrite the teleworker’s equipment and software. Some put the burden fully on the teleworker, some underwrite the required pieces, and some supply the teleworker with a pre-loaded, “approved” workstation. Factors that go into this decision include: data interoperability, teleworking budget, security, maintenance costs, and use as a recruiting/retention discriminator. To protect sensitive company information, teleworkers are frequently connected to their company’s intranet via a Virtual Private Network or a direct modem connection. Equipment expenses include (to the extent underwritten by the company):

- Computing equipment and software
- Office equipment (telephone, answering machine, cell phone, pager, copier, scanner, FAX)
- Office furniture (desk, chairs, file cabinets, bookcases, lights)
- Telecommunications (telephone, cellular phone, and cable connections; Internet access; Virtual Private Network)

The assets costs will go up as a result of buying new equipment. On the other hand, the working space cost will tend to be lower. When one of the departments of a

company move from an urban district to a rural one, the space cost will go down because of the lower price of the location and the local government’s grant.

Another problem we cannot ignore is the leaving unused of the assets. In the teleworking form, the leaving unused of the assets is inevitable sometimes. For example, when an employee chooses the home-based teleworking—three days working at home and the other days working at the main office, the leaving unused of the assets is serious. When we take opportunity cost into account, the assets cost will rise dramatically.

So, the assets cost can be expressed as

$$\text{Assetscosts} = \text{Equipmentcosts} + \text{spacecosts} + \text{opportunitycosts}$$

#### 4.1.2 Management costs

Telework, in any form, has ramifications beyond simply changing the way or place in which an individual employee performs work: It can extend to remote managing and virtual teams. Remote managing occurs when managers are physically separated from their members who work away from the main traditional office and communicate with them by information technology. Virtual teams consist of team members who are geographically dispersed and who come together by way of teleworking technology. Each team member may be located in a traditional office setting, but the offices are not proximate to one another. Additionally, virtual team members may telework, such as a teleworker who is a member of a multiple-site team.

Thus, telework may have additional challenges that emerge when consideration extends beyond the isolated telework—both up (to managers) and across (to teammates) the traditional organization. These challenges mainly resulted from the following several inherent obstacles:

- Only certain kinds of work are appropriate to perform at a distance
- Teleworker socialization needs are difficult to satisfy
- Non-telecommuting co-workers may resent the teleworker
- Electronic communication fails to substitute for face to face contact perfectly
- Meetings become harder to schedule
- Emergency actions involving the telecommuter become harder to take
- Teleworkers may lose focus on the task at hand
- Managers have difficulty managing by results only

These challenges of management may be showed as:

- Performance monitoring
- Performance measurement
- Mentoring
- Synergy
- Managerial control

#### Organization culture

To overcome these challenges, managers have to devote more works than before. The management costs will rise following these works increasing. For example, the internal coordination costs will increase because the managers have to travel between the central office and the teleworking sites. When the managers give up these traveling and coordinate by information equipment, the costs will change in pattern but not in amount.

##### 4.1.2.1 Communication costs

Communication form of telework is much more different from traditional form and also can makes us describe obviously the advantage and challenge in managing teleworking model so we discuss it more in this subsection. We give our attention to three parts of costs: the costs of social communication within the organization, the costs of searching for information for decision and the costs of handling remaining ambiguity. To improve the communication affection and get enough information for each teleworker, the organization has to use many IT equipments and devote much time into these activities.

On one hand, the e-flow of the information brings the communication a higher speed. On the other hand, due to the lack of the effective communications in the teleworking organization, feelings of isolation and an inability to complete work tasks fully become the main disadvantages of teleworking for the employee. All these factors will be the main obstacle to establish the organization cultures in a teleworking organization. Additionally, the employees may have difficulty in completing work assignments as they have less access to the necessary equipment (i.e., photocopier or fax machine). So the opportunity costs of the communication and will be much higher than before.

##### 4.1.2.2 Coordination costs

The coordination costs include the costs of commanding—giving and taking orders for instructions or control—and the costs of project leadership. The cost of coordination largely depends on the way the relationship between the company and the dispersed unit is regulated and this, in turn, goes back to the types of tasks that have to be performed by the unit. Generally, this part of cost will be arising in a teleworking organization. For example, the internal coordination costs will increase mostly because the project leader has to travel between the rural and urban offices to give ‘face-to-face’ instructions.

The reason why we put the communication and coordination costs into the fixed costs instead of variable costs is that communication costs in teleworking vary little, almost stable during the period. In the traditional working form, it is easy to communication costs vary

with output. If the teleworking is adopted, the e-flow and IT equipment will make costs more stable compared with the traditional working.

##### 4.1.3 Information costs

Information costs is shown on the marginal costs in the traditional model and it is covered into other costs such as the office’s rent. When teleworking is adopted, the information costs emerge clearly and the costs may decrease more and more by using IT equipments. Another reason of the decreasing of this part is that the distance between consumers and markets gets closer and closer in teleworking model. Here we give the definition of the information costs in telework that is produced when information is collected, transferred and switched by IT equipments for operating.

In addition, we must point out that the management and information costs have some superposition inevitably. For example, we cannot classify the cost when a manager exchanges information with a teleworker for daily work. However, when we refer to the information costs, we pay more attention on a teleworker rather than the manager.

#### 4.2 Variable costs

Compared with the fixed costs, we mainly discuss the variable costs from the aspect of an individual employee. In other words, we mainly examine the average costs of every teleworker.

##### 4.2.1 Marketing costs

About marketing costs, we must distinguish two kinds of conditions. First, if the marketing task is the project leaders’ job, such as in some consultant companies, the marketing costs with the client will keep stable due to the project leaders remain at the old location.

However, if the organization has the specific department to market with the client, the marketing costs may decrease especially when the purpose of organization’s executing teleworking is to reduce the distance between the company and the customers. In these cases, it is possible to locate part of the company close to an important supplier or customer, which could lower cost. Under these conditions, the satisfaction degree of the client will rise and the opportunity costs of marketing also go down.

##### 4.2.2 Travelling costs

The most obviously benefit for the teleworker from teleworking is the reduction of the traveling costs.

Studies show that Teleworking Programs can contribute to 60% fewer driver miles, and traffic congestion is reduced as the number of employees physically traveling

to their places of employment decreases. It is estimated that each driver could save two hundred gallons of gasoline and four quarts of oil each year by utilizing alternative work places.<sup>[7]</sup>

On the other hand, this travel-time reduction may result in over two hundred hours saved annually—time which can then be spent on family, hobbies, and other activities.<sup>[7]</sup> So we can get that if an employee choose telework, his/her opportunity costs of the traveling will be much lower than before.

#### 4.2.3 Training costs

In an organization, it is critical that both supervisors and employees feel they can share their concerns, and that they are capable of communicating their concerns cogently. However there are many difficulties in how to act as a qualified teleworker and how to manage teleworking when a traditional organization changes to telework. So it's necessary for managers and employees to improve their ability to make use of the electronic media for communicating effectively by training.

Supervisors of teleworkers provide important leadership, coordination, and team-building functions for their project teams. An introductory training session for telemanagers is recommended to:

- Learning the best practices of teleworker management
- Reviewing organizational telework policies and guidelines
- Understanding the needs of the teleworker
- Surface any concerns they may have about teleworking arrangements

Better-informed people make better-informed decisions. Introductory training for teleworkers helps inform them of:

- Organizational telework policies and guidelines
- Their communication responsibilities
- Best practices of telecommuting
- The challenges of to be a teleworker

Thus, for a teleworking organization, at the beginning of operating there must be a huge budget for the training costs. But when the managers and employees in the organization have been similar with teleworking, the training cost will be lower than before because these trainings can go on the teleworking web.

#### 4.2.4 Production costs

The impacts of teleworking in the production costs including the following aspects:

Most readily apparent is an increase in employee productivity. While such results may be based partially on subjective assessments, many companies report productivity increases ranging from ten to forty percent.

Similar increases have been reported in positions such as data entry clerks, where gains may be objectively measured.<sup>[8]</sup> While some may believe these gains result from employees working longer hours, a better explanation may be that teleworking (i.e., home) creates an environment more conducive to work. The teleworker is not subject to constant interruptions for quick questions or chats during the workday. Thus, the actual time spent working outside the formal workplace can produce a higher quality and quantity of work output. In addition to an increase in productivity, a decrease in absenteeism can be anticipated. Many absences occur due to an employee not being able to come to work for reasons including minor illnesses, emergencies, or personal appointments. When employees are able to perform some of their work as teleworker, absenteeism decreases, thereby minimizing the total costs.

The option of teleworking creates incentives for employees to remain with the company and thereby increases the retention rate and decreases recruiting costs. At the same time, teleworking allows the company to increase its base of potential employees, since the geographic location of available candidates greatly expands.

All what we have discussed as the above are explicit affections for a teleworking organization. However there are other advantages of teleworking existing as externalities for the company. Therefore, We should not be surprised when the government give a teleworking organization the grants. And the grants also affect the costs in teleworking just as what we point out in the next part.

#### 4.3 Application of the model in decision

How should a company decide whether a task is suitable for teleworking with a given work? Suppose there is a task  $T$  for a company. If we will complete the task with teleworking, we need  $n$  employees and  $t$  unit times. The fixed costs are  $C_f$ , and the average costs of variable costs for every employee is  $C_v$  per one unit time. The government grants are denoted as  $G$ , and the expected profits of the task are  $\pi$ .  $R$  is the opportunity cost of capital. In other words, the correct value for  $R$  is the return rate that the company could earn on traditional condition.

Then we can use the net present value (NPV) criterion to make decision:

$$NPV = \frac{\pi}{(1+R)} - C_v * n * t - an(C_f - G) * t$$

where  $an(C_f - G)$  is the annual cost associated with fixed cost minus the government grants.

The company should adopt teleworking only if that net

benefit is positive—i.e., only if  $NPV > 0$ .

## 5. CONCLUSION

In this paper, we divide the operating costs in teleworking into several parts. Then according to the different characteristics of every part, we adopt different method to analyze it and build the model. And we design a mathematical model to support making decision according to this model when an organization plans to adopt teleworking in it. However there are still many problems we cannot give an effective method to solve. For instance, when we come to the opportunity costs of capital, no one can give an accurate value about  $R$ . Under this condition we must ask for help with our experts. But, we are not certain with to which extent the estimated value is reliable when facing a new thing. All these suspending problems are interesting and challenges for us. Following with the development of teleworking in China, our society will pay more attention on this field.

# The Virtual Service Value-Chain: Disruptive Technology Delivering Competitive Advantage for the Services Industry

**John Hamilton**

Director of E-Business, James Cook University, Cairns, Australia 4870

John.Hamilton@jcu.edu.au

## ABSTRACT

Services have been investigated from a diverse range of approaches. Services encapsulate over 65% of global business, yet there are many gaps in the services knowledge base – particularly from an operations management perspective. This research investigates an emerging and truly disruptive business scenario – the service value-chain, from both a marketing and an operations approach. The service value-chain is defined as the flexible, dynamic, delivery of a service, or product, by a business's coordinated value chains (supply chains and demand chains working in harmony), such that a value-adding, specific, service solution is effectively, and efficiently, delivered to the individual customer.

The 'virtual service value-chain customer –business encounter model' is developed. Impediments to the development of a service value-chain are investigated to delineate future areas of business research. The virtual, information aspect of the services value chain customer 'touch-point' across the web interface offers a raft of new research possibilities and possible new pathways to competitive advantage. Eight key areas related to websites are offered as investigation areas. Business response mechanisms to the customer 'touch-point' must be focus on the competitive mix of strategic features.

**Key Words:** Services, Logistics, Service value chain, Strategic intelligence, Website, Customer

## 1. INTRODUCTION

The services industry provides services not goods[1]. This industry is moving towards globalization[2]. In 1870 the service sector employed slightly more than 20% of the U.S. workforce, whilst by 2002 it employed in approximately of 82% of the U.S. workforce, and 81% of the private sector GDP[3]. Services Management is a 'transfunctional' research area[4]. It covers areas including service quality[5], services encounters[6], and service execution[7]. Services operations management and services marketing provide other perspectives to services.

Definitions of service (and what constitutes a service) range from the narrow to the broad. In 1960 the Definitions Committee of the American Marketing Association (1960) defined services as: 'Activities, benefits, or satisfactions which are offered for sale, or are provided, in connection with the sale of goods'.

Examples of a service include: amusements, hotel service, electric service, transportation, the services of barber shops and beauty shops, repair and maintenance service, and the work of credit rating bureaus.

Judd[8] and Rathmell[9] promoted the service sector of the economy, and the true nature of services. Murdick, et al.[10] and Quinn, et al.[11] broadened services definitions to include all economic activities where output was not a physical product or construction, and was usually consumed when produced, and delivered as an intangible, added value to the customer - for example, travel comfort. Again services were redefined.

'Services are deeds, processes, and performances' [12], but they may also be tangible. Czinkota, et al.[13] split services into tangible areas involving: 1) people (fitness centres); or 2) possession processing (like freight transportation), and intangible areas involving: 3) mental stimulus like (education and religion); and 4) information processing (like banking, data processing). Often services are integrally enmeshed with manufactured goods, or to the delivering (or enabling) of goods. Thus the distinction between goods and services is imprecise, and no clear boundary between manufacturing and service firms exists[14]. According to Levitt[15], 'There is no such thing as a service industry. There are only industries whose service components are greater or less than those of other industries. Everybody is in service.' Taken to its logical conclusion, it could be suggested that all manufacturing is indeed a service, as it delivers something!

Encyclopedias including Britannica, Encarta, Columbia; and dictionaries including Oxford and Macquarie, offer a range of definitions of service. To meet these diversities we follow Rust & Metters[16] 'topologies' approach to group some of the complexities of services down onto models.

## 2. SERVICE TYPOLOGIES

From an operations and marketing perspective topology schemes for services have generally lacked empirically tested works. Empirical works [17],[18],[19], offer some key exceptions, but overall empirical services related research is in its infancy. A topologies approach, based on recent service industry models identifies key

knowledge gaps, and establishes possible empirical research areas.

### 3. SERVICE MODELS

Figure 1 presents Rust & Metters view of services. They grouped service models as customer models (external) or service provider models (internal).

Each model was then segregated, as shown in Figure 1, into two of the three models:

- 1) 'customer behaviour models' - dynamic models of customer retention (like loyalty) and stochastic models of customer behaviour (like satisfaction), and of customer behaviour (like churn rate or loss of a specific customer during a single service encounter);
- 2) 'service quality impact models' - aggregate models (like customer satisfaction effects) and disaggregated models (like financial impacts of a service component);
- 3) 'normative service models' - organizationally focused marketing models (like incentive schemes and trade-offs between satisfaction and productivity), and operations models (like queuing).

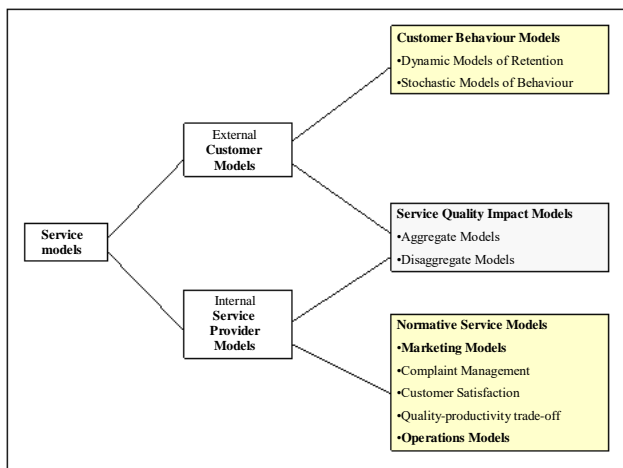

Figure 1. Mathematical Models of Service, from Rust & Metters (1996)

In 1999, Cook Goh & Chung[20] developed the 'integrated schematic representation of services' matrix. Figure 2 displays this integrated services schematic.

They recognized that services could be split into marketing (product) or operations (process) orientations. They believed that in delivering a final 'customized' solution their remained a need to integrate and interact with both orientations. They suggested research in the 'interaction and integration' area may articulate strategies and tactics for improving services.

Roth & Menor[21] delivered a further addition to the services topologies. Their 'service strategy triad' (displayed in Figure 3) separated the 'what', the 'how', and the 'who' of service encounters. It offered a new

perspective to advance an understanding of services operations management. The 'who' was the right customers (and not just a customer segment). These targeted customers could be defined by techniques like Forrester's 'technographics', 'psychographics', and psychographic profiling groups of customers. The interpretation of such target markets provided a means to enhance both service and performance standards, and to allow the business to competitively align its chosen degree of customer targeting with its offered service products and delivery systems.

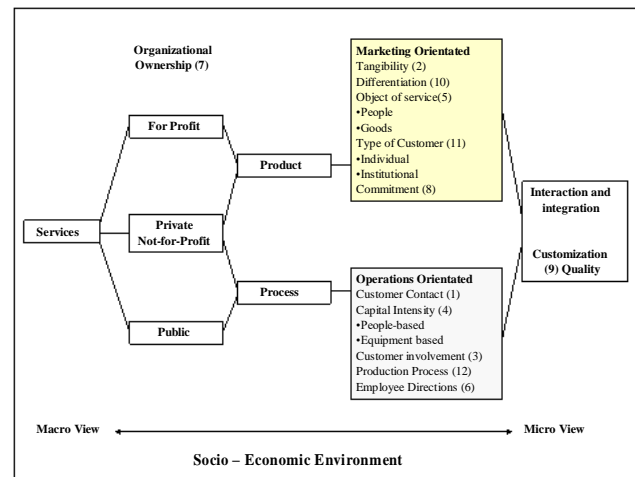

Figure 2. Integrated Schematic Representation of Services, from Cook, Goh & Chung (1999)

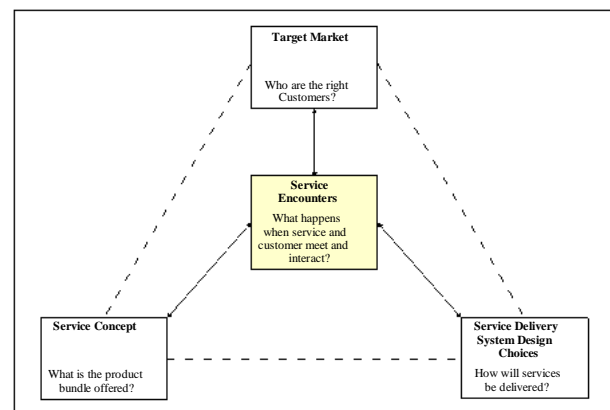

Figure 3. The Service Strategy Triad, from Roth & Menor (2003)

Roth & Menor operationally defined their 'service strategy triad' into 5 elements:

- 1) the supporting facilities (physical and structural resources);
- 2) the facilitating goods (materials and supplies that are consumed);
- 3) the facilitating information (supporting the explicit services);
- 4) the explicit services (customer experiential and sensual benefits);
- 5) the implicit services (psychological benefits).

They realized the total service concept by the customer, may differ from the service offered by the service provider. To overcome this, a feedback loop (execution, assessment of gaps, renewal) was proposed.

Roth & Menor's 'service delivery systems architecture' model, displayed in Figure 4, allows a framework to investigate three interrelated and dynamic components of service delivery systems:

- 1) the strategic service design (portrayed as structural, infrastructural and integration, and based on choices between time-phased content portfolios of major supply
- 2) the service delivery execution system (exemplified by programs, policies and behavioural aspects deliver complimentary areas of customer focus], possibly using balanced scorecard approaches;
- 3) the customer perceived value of the total service concept (intangibles and other effectiveness aspects of the service).

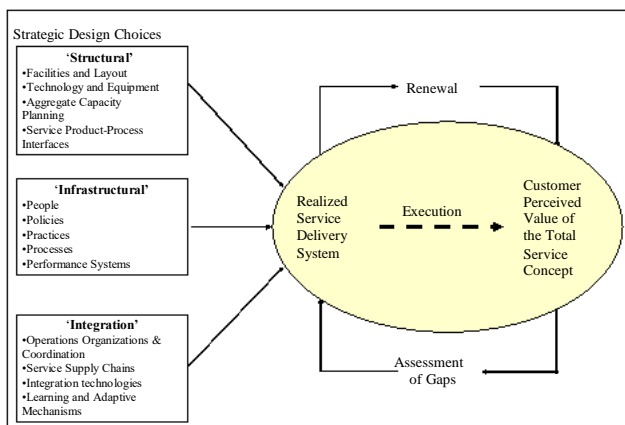

Figure 4. The Service Delivery Systems Architecture, from Roth & Menor (2003)

These features, delivered upstream by the external integration of the service supply chain, combined with the linked internal integration of the operational functional areas, and the adaptive mechanisms available to the intellectual capabilities provide new avenues to perceived customer value. Here the artificial learning and intelligence capabilities of the system, the fuzzy logic approaches to approximate answers, and the rapid absorption of skilled human capital talents may deliver targeted boundaries which offer enhanced potential to the service encounter. The assessment execution and renewal factors encountered define the potential effectiveness of the realized service encounter. These choices are the basis for forming competitive capabilities, in such strategic arenas as the internet, the manufacturing arena, internet marketing, and the services area.

The degree of service competitive capabilities such as consistent quality, supply chain management, convenience, accessibility to channels, customization, one-on-one customerization, operational efficiency and low costs are used by customers to make choices among competitors.

The above models, when considered with other factors like customer demand-driven supply chains, the effect of the internet, business solutions, virtual service organizations and technology options, along with their interrelated, and interconnected links, can be drawn into a new topology model termed the 'service value-chain encounter model'.

#### 4. SERVICE VALUE ENCOUNTER MODEL

The 'service value-chain encounter model' offers the framework for a new research model. This model is displayed in Figure 5. The operational, services and customer strategies of the business are drawn together as interconnected data sharing models delivering unique customer services encounters – ones aiming to exceed customer expectations! This business system learns from its customer encounters, and improves its services database offerings ready for additional, or more specific, customer encounters.

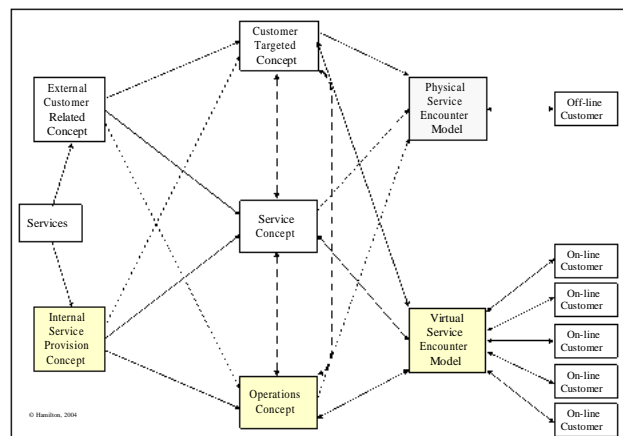

Figure 5. The Physical & Virtual Service Value Encounter Model © Hamilton (2004)

This model meshes with:

- 1) earlier works above;
- 2) other works[22],[23],[24];
- 3) commercial services business solutions providers [25],[26];
- 4) software developers including Microsoft & IBM.

The 'operations concept model' component delivers the business's latest service value-chain networked information systems, data storage and retrieval systems. It incorporates latest web metrics[27], fuzzy logic[28] and artificial intelligence[29] tools, to:

- 1) interrogate its internal and external databases;
- 2) sort and interpret available information;
- 3) deliver customized (or personalized) solutions capable of targeting perceived physical or virtual customer expectations.

This 'renewal' and learning networked system is very different to the normal 'rigid core component'

experienced in normal website service offerings[30]. It also incorporate issues related to failures and recovery [31]. In short, the 'operations concept model' component delivers the 'how' to the service value encounter.

The 'services concept model' component is integrated with both the operations concept model and the customer targeted model and delivers multi-dimensional information from the business and its value adding partners, in a quality manner, such that the greater the depth of information sought, the greater the quality, and the more realized[32] is the customer's experience. In short, the 'services concept model' component delivers the 'what' to the service value encounter

The 'customer targeted model' component establishes a relationship to the service being offered in terms of its efficiency, relevance, scope and performance[33]. This requires the cognition to recognize, and then target, the specific customer group. In some cases it allows for degrees of customization (or even one-on-one 'customerization'), of the customer service product. The understanding of the target market(s) remains an important consideration as it enables a viewpoint for new service development [34]. In short, the 'customer targeted model' component delivers the 'what' appropriately targeted to the 'whom'.

These three component models and their downstream areas house much of the business's intellectual property. They remain integrally linked downstream via a modern 'service value-chain'. Downstream business supply chain partners, logistics support, peripheral partners and other external data sources are interconnected and interrogated across the business integrated IT networks. Here internal and external data, logistics, and the like are pooled, shared, cross-model, and then applied to provide new business systems learning, and new, improved, upstream customer solutions. The customer and the business network come together at the service encounter 'touch-point'. Thus, the business aims to deliver the 'best', customer demand chain driven, customer value chain response, possible from the available value adding set of databases at its disposal.

The 'service encounter' has two components –

- 1) a 'physical' (tangible) encounter between the customer and a business contact person or persons;
- 2) a 'virtual' (intangible) encounter with and electronic based structure, which is often visually connected via its internal or external business website. In both cases information flows from customer to business and business responds sourcing relevant, allowable (non-sensitive), correct information.

Business then delivers customer requested, value chain sourced information (in a timely flow), across the service encounter interface and through to the customer. Chinese University of Hong Kong and National Sun Yat-Sen University research [35] indicates customers in the US

buy using multiple channels - including stores, catalogues, and on-line activities. The service value-chain operates across both physical and information pathways and networks. It is a key part of the operations management equation. Such viewpoints support the physical and virtual service value encounter model. Sterne [36], a world authority on web metrics, supports the notion that businesses offering both the physical and virtual encounter options tend, in the current market to be more successful, but that both models may also operate independently.

Businesses today are increasingly developing extensively networked on-line offerings, combined with high levels of interconnectivity between partners, alliances, and associated value adding organizations. In addition, they are moving their supply chains into high-tech, networked, intelligent solutions – termed service value-chains [37]. The 'service value-chain' may be defined as the flexible, dynamic, delivery of a service, or product, by a business's coordinated value chains (supply chains and demand chains working in harmony), such that a value-adding, specific, service solution is effectively, and efficiently, delivered to the individual customer in a physical or virtual manner.

In 2003, Australia's 'business to business' and 'business to consumer' e-commerce was valued at \$11.3B [38], and it was growing rapidly. It ranked 5<sup>th</sup> in the world regarding its potential to use the internet economy! At this time, thirty five percent of Australian businesses purchased on-line and eighty nine percent of Australian businesses were on-line. Australian businesses (with more than ten employees) recorded near ubiquitous internet adoption [38]. The internet has transformed many of Australia's key business and agency functions including services delivery, customer relationship management, organizational administration, supply chain management and knowledge (or data) management. In January 2004 over forty six million web servers worldwide were globally connected to the internet, with

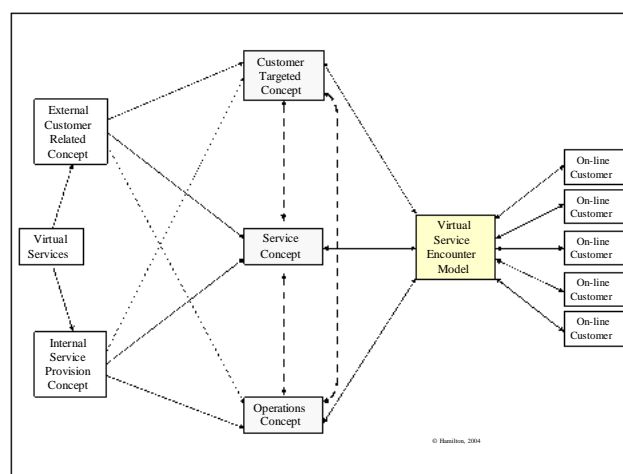

Figure 6. The Virtual Service Encounter Model © Hamilton (2004)

ninety six percent connecting with the browser Internet Explorer. Thus, for many countries like Australia the opportunity remains to deliver high-value service offerings to virtual business customers.

The business website presents one form of the 'customer service value-chain encounter model' – the 'virtual service encounter model', and it is displayed in Figure 6. This e-service encounter environment presents several potential virtual customer services related weaknesses and several points of research including:

- 1) amplification effects;
- 2) e-services;
- 3) the web interface;
- 4) value chain modelling;
- 5) customer targeting;
- 6) information communication technologies;
- 7) bottleneck effects;
- 8) business strategies.

These factors are elaborated below.

#### 4.1 Amplification Effects:

The bullwhip effect is defined as the 'phenomenon where orders to the suppliers tend to have larger variances than sales to the buyer (demand distortion) and the distortion moves upstream in a amplified form (variance amplification)[39]. Lee, et al.[40] consider customer ordering as a lumpy occurrence to which the supplier responds. Schmenner[41] theorized that fast, even-flow could explain productivity gains in manufacturing settings, and that even flows were achievable when the variability in supply chain was reduced. He also noted that tight quality control reduced negative amplification effects. Finch[42] states; 'a key to eliminating the bullwhip effect and a key to any supply chain management effort is an increase in 'information' supplied by business to their suppliers'. Thus the upstream amplification (or bullwhip) effects may be reduced where a website delivers more efficient, more direct, targeted, more uniform, information access pathways between the service value-chain and the customer. Improved information flows - delivering manageable amounts of filtered most relevant information to the customer may deliver one solution.

#### 4.2 E-Service Effects:

Many market forces influence the development of the service value-chains. There is an ever-present economic imperative to reduce IT costs, whilst increasing both the business value, and impact of this IT suite. Many businesses cannot afford high degrees of IT customization, and indeed this may not always be necessary – consider a mass user situation like on-line airline bookings. Hence size and capital remain limiting factors. Timelines to move to on-line service value-chain solutions also vary.

A true service value-chain integrates all aspects of its business's service supply chain – internal and external in an intelligent, coordinate manner. It then interrogates the relevant data and delivers business-specific intelligence that matches the demands of the customer, again reducing inefficiencies. This area remains one with great scope for further research and development. Various third party logistics solutions have been developed to integrate these areas with those of other businesses, delivering new strategies, solutions and competitive advantage.

#### 4.3 Website Effects:

Incorporating software programs that query the available database information apparently 'intelligent' solutions to customer requests may be offered.

The intelligent website acts similarly to an intelligent, inquisitive, reasoned, language sensitive search engine, capable of taking in customer requests by voice, email, image, 'search-for ...', and the like. Artificial intelligence, knowledge management, and fuzzy logic principles are then applied to determine efficient, appropriate business-specific solutions.

The resulting 'intelligent' website processes may reduce the need to revisit and reinterrogate databases, and may reduce the non productive, time consuming, information seeking workload requirements on the service supply chains. Significant, tangible and intangible cost reductions (less non productive website activities) may be achievable. Less demands, per initiative, per customer, may reduce the information transmission strain across the global communications networks, and may reduce negative customer sentiment.

Such solutions may require the flat website encounter to move to a new three dimensional approaches[43].

#### 4.4 Value Chain Modelling Effects:

Value chain modelling[44] has shown how changes in speed, responsiveness, and variability affect operational performance, and may enable the business to perform solutions scenario like financial impact assessment, cost-benefit analysis, and sensitivity analysis.

Vermijmeren[45] suggests flexible, intelligent supply chain 'engines' may drive these dynamic supply chains, delivering value, in an efficient manner. Various third / fourth party logistics additions offer additional new strategic solutions, scope for competitive advantage, and scope for business development.

The incorporation of peripheral added value options may improve these offerings.

#### 4.5 Customer Targeting Effects:

When a customer encounters any aspect of a business a 'moment of truth' arises, and positive or negative impressions can be generated[46]. In highly customer responsive business systems, customer contact time may be lessened and sales opportunities may be enhanced. The customer may be an internal customer (working for the business, a participant in the upstream service value-chain, or an internal services participant in an area such as data processing, engineering, maintenance, accounting, after sales service[47], or an external customer (a consumer or one who interacts with and adds value to the business service value-chain. To service the virtual customer complete, responsive, flexible, adaptive, service value-chains often offer most desirable options. Finch argues that delivering quality services involves assurance and empathy. However to deliver service quality across a website requires a broadening of the quality dimensions to encapsulate product and service and product dimensions. Thus the customer exhibits a multidimensional impact on the business website. Hence, the business must maximize its virtual 'touch-point' appeal, and must develop its virtual management tools (and strategic metrics) set.

#### 4.6 Information Communication Technology Effects:

In 2001, the five largest software providers: HP, IBM, Microsoft, Oracle, and Sun, along with a few new entrants, began promoting new standards, new web services platforms, and new activities environments. Since 1998 internet protocol version 6 (IPv6) software has been encapsulated into operating systems platforms[48]. If adopted, IPv6 will allow marketers to segment a business's website customers using postcodes, geographical location, and phone numbers. Mobile devices, watches, and clothing, are now capable of housing customized information solutions for business. Third party software operating on common platforms like Microsoft's '.Net', or IBM's WebSphere platforms may further enhance the virtual environment delivering savings for business measured as per initiative - lower 'human', and 'capital resource requirements'. In addition, new ways to interpret, interrogate and deliver customer requirements are unfolding, and highly intelligent, responsive websites are emerging. New business strategies, and the nuances of customer wants and needs are developing and will be incorporated into solutions. Working relationships - like 'e-customer relationship management', trust, loyalty, satisfaction, addressing the dynamics of the industry structure, and cultural fit will become just as important to the customer as the provider's portfolio. Currently latest computer application tools deliver low level solutions (not high levels of customization), and are best utilized for standard product type applications. Hence the development (and implementation) of highly customerized, and fully operational, 'service value-chains' is not yet a reality.

#### 4.7 Bottleneck Effects:

Bottlenecks occur when a limiting resource affects the output level of the entire system. The business-customer website encounter as shown in Figure 6, is one such bottleneck. Here, multiple customers search multiple supply chain data sources, for their individual needs, and business inefficiencies arise. Finch suggests bottlenecks may be considered as business constraints.

In the services industry, information is the key ingredient that moves. Some information may be physical in nature - like paperwork, whereas in the manufactured product situation, both information, and product move. In both cases information bottlenecks occur.

Efficient design of the website (with the use of appropriate technologies), may reduce customer cycle-time (customer website access time to source, retrieve and absorb desired information) [49],[50], reduce bottlenecks, and possibly improve website effectiveness. Thus 'touch-point' information trade-rates between the customer and the business service value-chain remain dependent variable areas that may be improved.

#### 4.8 Business Strategies Effects:

Businesses faced with tough competition are devoting greater resources to support their e-business initiatives [51]. Using tools defined by IBM and others these businesses can prioritize their financial and operational performances, and closely define their e-business and management strategies in multiple-customer environments. These strategies involve the development of semi-intelligent websites, and target delivering in four key areas related to the 'physical and virtual service encounter model' - these are the: 1) technical (operations model) factors - including communication channels; software and hardware; artificial intelligence; fuzzy logic methodologies; natural language interpretations; web metrics; website flows and information integration; presentation modes (3D screens); and telepresence. 2) business (service operations model) factors - including externals - supply chain partners; peripheral partners; logistics; and internals - business, management; marketing; operations; and strategies. 3) customers (customer targeting model) factors - grouped initially in technographic segments, then cyber-segmented further to eventually allow individual targeting. 4) revenue generator factors - including - sales, fees, charges, advertising, partnerships, and franchises.

### 5. BUSINESS RAMIFICATIONS

An understanding of the 'virtual service encounter model', and its 'effectors' provides the business strategist with a new disruptive business model. This model facilitates the development of inter-service-model concept measurements, and relevant integration processes.

Each business has a unique mix of effectors and further research in this area is currently being pursued by the author. Investigation is continuing on 5 fronts – customer targeted constructs, on-line customer constructs, serviced concept constructs, operations constructs and financial constructs. The aim of this research is to deliver a new customer touch-point model, one that delivers greater satisfaction to the virtual customer and does so in a more efficient manner, by better developing and utilizing the service value-chains. This will ultimately deliver a highly agile, flexible service value network, and do so at reduced financial commitment per virtual customer.

## 6. CONCLUSION

The ‘physical and virtual service encounter model’ provides a service value-chain view of areas where a business may attempt to close the gap that exists between ‘business issues’ in the client side and ‘technology capabilities’ in the provider side. The virtual customer ‘touch-point’ is complex, and many areas of research, development and idea creation may be applied to enhance the business’s website competitiveness [52].

Hence the realm of business, its virtual service value-chains, and its virtual customer remains an exciting area of investigation. This paper delivers many related opportunities for research and business development and scholars are encouraged to join in developing this emerging field of research and disruptive technologies.

## ABSTRACT

This paper presents the Web services applying on a shopping automation across the Internet from portable mobile devices accessed by users. First of all, a shopping automation is considered as hardware system such as embedded device products. They are binding with web in some protocol. Another hand, the portable mobile devices also connected with web in WAP protocol. We model them in Web Services Description Language (WSDL) to represent such environment system. An example is described in this study that includes a General Packet Radio Service (GPRS) platform is used as the function of home gateways. In addition, an XML-based protocol is defined as the interface between web server and shopping automations.

**Keywords:** shopping automation, WAP, WSDL, GPRS, XML-based protocol

## 1. INTRODUCTION

Web services are more important with increasing the number of portable mobile devices, such as mobile phones, Personal Digital Assistant (PDAs). A typical Web services architecture consists of three entities, including service providers, service requesters, and service brokers [9]. Service providers create Web services for service requesters. These Web services are registered in service brokers and the brokers handle the requesting from service requesters and find published Web services of service providers. Hence, efficient access to Web services became an important issue. Ouzzani and Bouguettaya provide a query optimization model based on aggregation the quality of Web service parameters of different Web services [8]. In addition, Web services consist of three important protocols. First of all, Simple Object Access Protocol (SOAP) provides a simple and lightweight protocol for communicating between Web services and client applications. Next, Web Services Description Language (WSDL) is an Extensible Markup Language (XML) based language to be used for describing Web services. Furthermore, Thomas et. al use Petri Nets to model the WSDL [13]. Finally, the Universal Description Discovery and Integration (UDDI) is used to let Web services register their services for services requesters. In order to test and evaluate Web services, Tsai et. al provide an XML-based Framework that consists of test master and test engine [12]. The former allows testers to specify test scenarios and cases converted from WSDL specifications. After the Embedded Internet System (EIS) was proposed in 1998 [7], academic researchers in this field are increasing in number. For example, Szymanski [11], designed web that applied the EIS ideas to enable control webs to perform online monitoring. The Open Services Gateway Initiative (OSGi) [5], whose mission is to generate open

specifications for delivering of various services over wide area networks to local networks and devices was founded in March 1999. The three core aspects of the OSGi mission are servers, various networks, and devices. In 2000, Topalis et al. implemented a home gateway to support automated home networks and home Internet connectivity [14]. In 2001, Saif et al. proposed a self-configuring software architecture for home area networks, which provides an extensible markup language (XML) based registry and a hypertext transmission protocol (HTTP) based event service [10]. In 2001, Filman applied an embedded computer to design a home gateway, because embedded computers had progressed from being simple machines to being "thinking" and sensing" machines [3]. Furthermore, Chen et. al in 2002 provide an XML-based graphical monitoring protocol for distributed systems [2]. In 2003, Kapsalis et. Al [6], used the technologies Object Link for Process Control (OPC) enable Internet access, and proposed a gateway to integrate various services. Although a large number of studies have been made on both Web service and home automations or shopping automations, little is know about integration of both. The first aim of this study is to develop a web-based monitoring system for providing Web services. The remainder of this article is organized as follows. Section 2 presents the proposed system architecture. Section 3 introduces this Web representation in WSDL and a simple protocol is defined as the interface between automation server and shopping automations. A mobile shopping automation example is illustrated in Section 4. Finally, Section 5 draws conclusions.

## 2. SYSTEM ARCHITECTURE

A three-tier application has front-end clients (e.g., browsers), middle-tier application servers (e.g., web servers), and back-end databases. It is one where the

logical decomposition of the application is reflected both at the software and hardware level. Similarly, a mobile shopping automation system, including portable mobile devices, an application server, a database, an automation server, and a shopping automation network, is now constructed and show as Fig.1. The mobile device, the application server, and the database server can be regarded as a data process path, another way, the database server, the automation server and the shopping

automations can be regarded as being a signal process path. They have a common database for data process path and signal process path. Although such an integrated model does not yet have a common standard for mobile monitoring, the definitions of among layers are useful to clarify rules and developments of the interface protocol. The server described above is used to perform the functions of an application server and automation server.

Fig. 1. A mobile shopping automation architecture

### 3. WEB REPRESENTATION

Web representation is the main goal of this work. We'll analysis those operations and protocol parameters in mobile shopping automation. For Applying WSDL, a WSDL flow model is used to model our system to descript our Web services. Finally, an automation network protocol in our system is described herein.

#### 3.1 Operations and protocol parameters

Three operations are provided from application server to mobile user, including inquire, control, and push. A user can call on a web site to retrieve the sensor status  $T_s$  in the database. This procedure is called the inquire operation and is denoted as  $O^q$ . For the database,  $O^q$  is a read-only operation and so is a concurrent process. Next, a user can change the sensor status, and use a control operation to finish it. This control operation is denoted as  $O^c$ . It is not a concurrent process. This operation must cooperate with a mutual exclusion table to ensure consistency among data. Although database operations provide a transaction mechanism, an inconsistent state may occur. For instance, two users, A and B,

simultaneously change the status of a single sensor. The successive operations are  $O_a^q O_b^q O_a^c O_b^c$  and an inconsistency arises. An automation server is built to prevent the above inconsistency. However, the server can process concurrent problems. The data process path can simply prevent inconsistency because the server provides a mutual exclusion mechanism. The last operation associated with the data process path is a push operation. For a mobile system, two models can be applied, *pull* and *push*. For push operation, the application server actively sends information to a user's mobile device. SMS or MMS technology is employed to implement the push mode. Such an operation is denoted as  $O^p$ . Two operations are provided from automation server including *in* and *out*. The automation server extracts a control command from table  $T^c$  of the database and then sends the command to the sensor. The procedure to be used is denoted as  $O^i$ . Moreover, the server periodically reads the sensor status and then stores the status into the status table  $T$  and a message table  $T^m$ . This procedure is called *in* and is denoted as  $O^i$ . Then we draw them into the system block diagrams and show in Fig.2.

Fig.2. operations on mobile environment

Furthermore, we define a mobile control web operation set  $O^{mcw}$ , includes five primary functions.  $O^{mcw} = \{O^q, O^c, O^p, O^o, O^i\}$ . For the inquire operation  $O^q$  is used to represent an object embedded some parameters includes name, value, and protocol fields. The name filed is the name of the object. It consists of sixty-four characters and is unique to represent a primary key for

this object. The value field is also string type because it can represent a value of float and integer. In addition, using string also represent a binary status into {on, off}. Protocol field parameter  $P$  is used to carry application server communication with client. For operations  $O^q, O^i$ , the parameter of protocol field  $P^s$  is used to carry automation server communication with shopping

automations. We also define a protocol set  $P^{mcw}$  of a mobile control web includes two protocol parameters  $P^h$ ,  $P^g$ .

### 3.2 WSDL flow model

WSDL is an XML-based document includes specific elements: types, message, port-type, binding and Service. It is used to describe what a web service can do, where it resides, and how to invoke it. In this study, we map the mobile shopping automation environment to WSDL as shown in Fig. 3. In this figure, there are two ports, port-c and port-s. The former uses WAP protocols to bind between a mobile client and an application and the latter is used to bind a sensor network and an automation server using sensor protocols. The protocol

Fig.3. A mobile home automation for WSDL flow

Fig.4. The DTD of SN protocol

### 3.3 Sensor Network Protocols

In this section, we describe sensor network (SN) protocols in our system. The Document Type Definition (DTD) of the SN protocol is shown in Fig.4. There are two types of command elements: Digital Data In (DI), and Digital Data Out (DO) in this figure. Each command element has a device attribute. If a command is sent from a GPRS control platform to an appliance server, the device attribute is used to specify as the identification (ID) of the target device. If the command is sent from the appliance server to the GPRS control platform, the device attribute is used to store the ID of the source device.

```

<?xml version="1.0" encoding="UTF-8"?>
<!ATTLIST DI
  device ID #REQUIRED
  value (On | Off | Query) #REQUIRED>
<!ELEMENT DO EMPTY>
<!ATTLIST DO
  device ID #REQUIRED
  value (On | Off) #REQUIRED>
<!ELEMENT DI EMPTY>
<!--root element-->
<!ELEMENT SN (DI | DO)+>
  
```

### 4. EXAMPLES

The information server is constructed using server operation systems such as Windos2000 Server or Windos2003 Server, and application software for web pages and databases. A remote appliance monitor is composed. It has a control platform MA8-6 that

is defined in next subsection. In spite of port-c or port-s are used in GPRS wireless channels. When a request is send to the application server. Herein, the application is to play as a service broker. Hence, the application can find a suitable automation server from its Database registered by automation servers. When a application server is selected, it sends a query command to a specify sensor device in a sensor network through a GPRS channel. In our system, a sink node introduced by Akyildiz *et. al* [1] can receive the command and process this command to read the status of the specify sensor device. Next, the information of the specify sensor device backs to the automation sever by the sink node. Finally, the automation server provides this service, a required sensor status, to the mobile client that proposes this request.

contains multi-type I/O interfaces, DIO, RS232 or RS485, linked to the web's appliance server via GPRS protocols. This system can be used as a set of sensors to detect earthquakes, stealers, or fires. Appliance server access several numerous detector data and save to the public databases for information server sharing. The main effect of the application server is just to provide a html or asp.net webpage to supply an ideal interface between the web's database and the user of a cellular phone. The user can enquire about, and control the appliances from his or her cellular phone through the WAP or HTTP protocol. Figure 5 shows a sensor network that consists of anti-fire, anti-earthquake and anti-stealing circuit-board, and the GPRS control platform, MA8-6. Figure 6 shows the states of the appliances from database using an IE browser.

### 5. CONCLUSIONS

This study addresses an integration of web services apply on mobile shopping automations. We hypothesize that it can be treated as a both software and hardware architecture in order to model the relation between Web services and mobile shopping automation. The servers provide mobile Web services and automations controls. They are important roles in our system. The application server is a service broker, the automation server is a service provider, and a mobile client, mobile phone or PDA, is service request. The architecture of Web services for mobile shopping automation is represented. In addition, the GPRS mechanism and protocol of SMS can be used to achieve real-time monitoring functions for remote monitoring.

## ABSTRACT

Supply chain integration (SCI) among different trading partners within a supply chain (SC) has received increasing attention from academicians and practitioners in recent years. However, our knowledge of what influences or enables SCI between trading partners, and how integrations in the SC influence the performance of the SC and firms within the SC, is still very limited. In this paper, we develop and test the measurement instruments for SCI and performance. We also investigate the impact of trust, relationship commitment on SCI and the impact of SCI on SC performance. We propose and empirically tested a model of SCI using data collected from manufacturers within the SC from China. The results show that trust and perceived strategic importance of relationship with the supplier and customers significantly improve relationship commitment. Relationship commitment positively influences SCI and SCI leads to SC performance and the financial performance of the firm within the SC. This study provides important insights for future researchers to understand trust, relationship commitment and SCI from various perspectives.

**Keywords:** Trust, Relationship Commitment, Supply Chain Integration, China

## 1. INTRODUCTION

Though the fundamental concept and importance of supply chain management (SCM) are widely accepted by both the scholars and the practitioners, there is a dearth of empirical research investigating how trust, relationship commitment influence supply chain integration (SCI) and how SCI influence the performance of the supply and the financial performance of firms within the supply chain. Previous studies identified different types of integration of SC (Markham, 2001, Narasimhan, 2001, Stank, Keller and Closs, 2001, Johnson, 1999, Morash & Clinton, 1998). Some papers analyzed the relationship between SCI and SC performance (Narasimhan, 2002, Armistead, 1993). Morgan & Hunt (1994) empirically validated the hypotheses of trust and relationship commitment as key mediating variables in ten forms of relationship marketing for tire retailers as well as their suppliers from the relationship marketing perspective. Their findings generalized that trust engenders cooperation among SC, and that relationship commitment is crucial for integrating SC partners into their key customers' business processes and established goals. Handfield & Bechtel (2002) demonstrated how suppliers and customers could build relationships based on trust and their findings further suggested that working to trust could improve SC responsiveness. Beth et al. (2003) advocated that trust and relationship commitment are placed in the highest priorities in achieving "SCI", a significant concept that promotes collaboration between SC partners for values and competitiveness.

Chen & Paulraj (2004) developed a theoretical framework that integrates strategic purchasing, supply management, logistics integration, supply network coordination, and SC performance. They made a good

attempt to synthesize a large body of literature. However, failed to examine how trust and relationship commitment enable SCI and the paper did not deal with the explanations of various types of SCI. Our study aims to build a model to represent the relationships among trust, relationship commitment, SCI, and SC performance using data collected from manufacturers from Mainland China and Hong Kong. Specifically, the objectives of the paper are as below:

- 1). To define three types of integration: customer integration, supplier integration, and internal integration and develop an instrument to measure them;
- 2). To study the relationships among these three types of integrations and how they influence SC performance and the financial performance of the firm within the SC; and
- 3). To investigate how trust and relationship commitment influence SCI.

## 2. LITERATURE REVIEW

Extensive literature has attached great importance to SCI for achieving competitive advantages (McGinnis & Kohn, 1993; Clinton & Closs, 1997), as well as operational performance (Ahmad & Schroeder, 2001; Frohlich & Westbrook, 2001; Stank, Keller and Closs, 2001). Several researchers such as Bowersox & Morash (1989) and Hammer (1990) suggested that SCI is to integrate the relationships, activities, functions, processes and locations among all channel members in the SC. Stevens (1989) proposed that integrating the SC is primarily involved in planning, coordinating and controlling materials, parts and finished goods from suppliers to customers at all different strategic, tactical and operational levels. Vickery et al., (2003) suggested that SCI should be strategically managed as a single

system as opposed to individually optimizing fragmented subsystems. But, one of the limitations of the earlier explanations is that they may not be systematic enough to differentiate integration from SCM. SCI could be illustrated as the degree to which the firm can strategically collaborate with their SC partners and collaboratively manage the intra- and inter-organization processes to achieve the effective and efficient flows of product and services, information, money and decisions with the objective of providing the maximum value to the customer at low cost and high speed (Bowersox, Closs & Stank, 1999; Towill & McCullen, 1999; Frohlich & Westbrook 2001; Vaart & Donk, 2003). Morash & Clinton (1998) investigated and compares two types SCI: external (customer and supplier) and internal (process reengineering) integration for approximately two thousand global firms. Markham (2001) investigated supplier and customer integration strategies in a global sample of 322 manufacturers. Stank, Keller & Daugherty (2001) developed and tested an instrument for measuring SCI competences as well as evaluating their relative importance to developing logistic distinctiveness.

Collaborative relationships have become one of the most significant resources for building up competitive advantage (Dyer & Singh 1998). Much literature (Kumar 1996; Spekman et al. 1998; Bachmann, 2001) argued that trust is a useful lubricant or fundamental ingredient in maintaining cooperation and avoiding conflicts. Handfield & Bechtel (2002) found that trust could significantly contribute to the long-term stability of a SC. Understanding trust has become the top priority concern in upholding the relationships among SC partners. Trust can be conceptualized in two different levels: interpersonal trust and organizational trust (Cummings & Bromiley, 1996; Zaheer et al., 1998). On the basis of interpersonal trust, organizational trust is established. Organizational trust can be further classified into two categories: intra-organizational trust (Shockley-Zalabak et al. 2000) and inter-organizational trust (Zaheer et al., 1998). Although the issue of trust within the SC has not been studied until recently, the concept of trust has drawn considerable attention in management (e.g., Kramer & Tyler, 1995; Doney, Cannon, & Mullen, 1998) and other disciplines (e.g., Child & Mollering, 2003).

Barber (1983) and Morgan & Hunt (1994) suggested that the propensity for relational continuity and the establishment of long-term relationship are primarily in the theme of "relationship commitment". Relationship commitment can be defined as the willingness of a party to invest resources into a relationship (Dion et al. 1992; Morgan & Hunt, 1994). Gundlach, et al. (1995) further pinpointed its importance for developing and sustaining successful relational exchange. Mayer et al. (1995) and Luo (2002) also argued that the commitment is the backbone of strengthening the function of established trust. Relationship commitment can be identified into two levels: interpersonal commitment and organizational commitment (Hornby, 1995). Organizational

commitment could be further categorized into Intra-organizational (Porter et al., 1974; Mowday et al., 1982) and inter-organizational commitment (Cheng et al., 2004). With increased inter-organizational commitment, SC organizations would develop closer relationships with their SC partners; therefore, it enhances the implementation of SCI. There has been an increasing research emphasis on trust and relationship commitment in recent years.

Handfield & Bechtel (2002) studied the role of trust and relationship structure in improving SC responsiveness using data from North American manufacturing firms. They suggested that trust can improve SC responsiveness and developing trust within the relationship improves supplier responsiveness even if buyers do not possess great control over their suppliers.

As cited by Chen & Paulraj (2004), a common measure of business performance is financial performance because the primary goal of business organization is to make profits for the shareholders. Financial performance has been widely used as a key measure of firm performance (Boyer et al, 1997; Boyer, 1999) and is evaluated in different dimensions. However, much literature (e.g. Dixon et al., 1990; Eccles & Pyburn, 1992) has pinpointed the limitations in relying solely on financial performance measures in SC. A broader conceptualization of performance measures includes customer service and other operational indicators. Neely et al. (1995) presented a few of the categories of performance comprising quality, time, flexibility, and cost. Van Hoek (1998) further advocated the SC firms to devise innovative measurement system as opposed to the traditional ROI-based system. Beamon (1999) presented an overview and evaluation of the performance measures used in SC models and also presents a framework for the selection of performance measurement systems for manufacturing SC. Vickery et al. (2003) included the dimensions of service performance in their customer service construct. Several researchers (Kaplan & Norton, 1992; Maskell, 1991; Gunasekaran, Patel & McGaughey, 2003) suggested that a balanced approach for the performance measurements is essential to present a clear picture of organizational performance. Actually, some recent SCI studies (Tan et al., 1998; Vickery et al., 2003) have used both operational and financial performances as indicators for the organizational performance. However, many SCI studies have measured either operational (Scannell et al., 2000; Stank, Keller and Closs, 2001) or financial performance outcomes (Ross, 2002).

### 3. THE PROPOSED MODEL AND HYPOTHESES

Based on an extensive literature search and in depth interviews with more than 15 practitioners who are in charge of SCM in Hong Kong and Mainland China, we propose the following theoretical framework for SCI (Figure 1). Within this framework, we have included the

following eight theoretical constructs, (1) Trust (trust with customer (Ctrust) and trust with supplier (Strust)). Trust is defined as a willingness to rely on exchange partner in whom one party has confidence (Moorman, et al, 1992). (2) Relationship Commitment (to customers (Rcc) and to suppliers (Rcs)). Relationship commitment is defined as the enduring desire of committed party to sustain an important on-going relationship (Morgan & Hunt, 1994). (3) Supplier Integration (Si). Supplier integration refers to the core competence derived from better coordination of all the critical suppliers in a company's SC to jointly achieve improved service capabilities at lower total SC cost (Bowersox, Closs, and Stank, 1999; Lee 2000). (4). Customer Integration (Ci), Customer integration refers to the core competence derived from better coordination of all the critical customers in a company's SC to jointly achieve improved service capabilities at lower total SC cost (modified from Bowersox, Closs, & Stank, 1999). Customer integration and supplier integration can be looked as external integration compared with internal integration. (5). Internal Integration (Ii). Internal integration refers to the degree to which a firm can structure its organizational practices, procedures and behaviors into collaborative, synchronized and manageable processes in order to fulfill the customer requirement. (Leveraged from Kingman-Brundage et al. 1995; Cespedes 1996; Kahn & Mentzer; 1996; Chen & Paulraj, 2004). (6) Perceived Strategic Importance of Relationship Commitment (for customer (Psircr) and supplier (Psisrc)), (7) SC Performance (Scperf). SC performance is defined as the non-financial measures to evaluate the firm's customer responsiveness, such as SC cost, inventory level, quality, flexibility, lead-time, delivery, process time and speed, etc. (8) Company Financial Performance (Fperf). Company Financial performance is defined as financial and market measures to evaluate the firm's efficiency and effectiveness.

**Figure 1. Proposed model**

Trust and relationship commitment are salient and inter-related elements in structuring the inter-organizational interactions (Morgan & Hunt 1994) & Moore (1998). Based on the assumptions that the existence of trust reduces the perception of risk associated with opportunistic behavior and thus increases the exchange partners' confidence in the effectiveness of future relational exchange, motivating the exchange partners to commit in the relationship, Morgan and Hunt (1994), Moore (1998) and Ruyter et al. (2001) suggested that trust has an influence on relationship commitment. So we proposed the following hypotheses:

H1: Ctrust has a positive influence on Rcc.

H2: Psircr has a positive influence on Rcc.

H3: Strust has a positive influence on Rcs.

H4: Psisrc has a positive influence on Rcs.

With relationship commitment, SC partners become integrated into their key customers' business processes and more tied to established goals (Morgan & Hunt, 1994; Chen & Paulraj, 2004). Johnson (1999) investigated the strategic role of inter-firm relationships through the concept of strategic integration. Stank, Keller and Daugherty (2001) developed and tested the measures to examine empirically the relationships between internal and external SC collaboration and logistical performance. Daugherty (2002) empirically examined the role of relationship commitment based on closer buyer-seller relationships. So we proposed that:

H5: Rcc has a positive influence on Ci.

H6: Rcs has a positive influence on Si.

H7: Ii has a positive influence on Ci.

H8: Ii has a positive influence on Si.

The relationship between SCI and performance outcomes is discussed over a vast body of SC and operations literature (Colin & Mapes, 1993; Daugherty et. al., 1996 and Tan et al., 1998). For example, Armstead & Mapes (1993) identified the extent to which greater integration along the SC leads to improve operating performance. Stank, Keller and Closs (2001) developed and tested an instrument for measuring SCI competences as well as determining their relative importance to developing logistics distinctiveness. Stank, Keller & Daugherty (2001) suggested that collaboration with SC partners facilitates internal collaboration, which in turn enhances logistics performance. Frohlich et al (2001) demonstrated that SC companies with the widest degree of the arcs of integration achieve the highest level of performance improvement. So we proposed the following hypotheses:

H9: Ci has a positive influence on Scperf.

H10: Si has a positive influence on Scperf.

H11: Ii has a positive influence on Scperf.

H12: Scperf has a positive influence on Fperf.

## 4. RESEARCH METHODOLOGY

### 4.1 Sampling and Data Collection

To test the above hypotheses, we collected data from manufacturing companies in Hong Kong and Mainland China.

We selected five cities to represent China: Chongqing, Tianjin, Guangzhou, Shanghai, and Hong Kong. A mail survey combined with telephone calls was used to maximize the return rate. The questionnaire included questions on the demographic profile of the company and the questions related to the company's performance and SC performance, internal process integration,

customer integration and supplier integration, customer and supplier relationship commitments, and customer trust and supplier trust. For all these questions, a Likert scale of 1 to 7 was used. Before we launch the full-scale study, we piloted test the questionnaire using a sample of 15 companies. We revised the questionnaire based on the results of the pilot-test. We used the yellow pages of China Telecom in each one of the four cities in Mainland China and Directory of the Chinese Manufacturers Association in Hong Kong as a large sampling pool. We randomly selected the sampled companies from the lists and made telephone calls to these companies. Through the phone contacts, we make first make sure the company is a manufacturing company and then identify the right informant to fill out the questionnaire. We asked for the person who is in charge of supply chain management or the person who is knowledgeable about customer/supplier relationships and internal integration. We found the most suitable respondent is Supply Chain Manager, President, Vice President, or General Manager depending on the company. We get the company's permission to receive the questionnaire and name and address of the most suitable respondent for the survey. Then we sent the questionnaire to the most suitable respondent. A cover letter highlighted the objectives of the survey and its potential contributions to the respondents. Respondents were encouraged to participate in the survey with an entitlement to a summary report of the results. Self-addressed envelopes with return postage were also included together with the survey to facilitate the returning of the completed questionnaires. 4,569 companies were conducted via the phone and were identified to be manufacturers. A total of 1,356 agreed to receive the questionnaire and thus received the questionnaires. The response rate is 13.5% based on total manufacturing companies contacted and 45.5% based on the number of companies who received the questionnaire.

#### 4.2 Measures, Construct Validity and Reliability

In the study, we use structural equation modeling to estimate the causal relationships among the different constructs with linear structural relations (LISREL) program and a sample of 617 companies. LISREL 8.54 was used to analyze the hypothesized model. A two-step model building approach was used, wherein the measurement models were tested for the reliability and validity prior to testing the structural model. For the measurement models, Trust with customers construct is measured by two items adapted from the scale developed by Morgan & Hunt (1994). Perceived strategic importance of customer relationship and perceived strategic importance of supplier relationship are measured by four items respectively. We modified the items of strategic integration used by Johnson (1999) to assess strategic importance on SCI. Relationship commitment with customer and relationship commitment with supplier are measured by three items respectively.

We adapted the scale developed by Morgan & Hunt (1994). Customer integration, supplier integration, and internal integration are measured by eight items respectively. The scales were largely derived from the items of Narasimhan & Kim (2002), Morash & Clinton (1998), and Narasimhan & Kim (2002). SC performance is measured by seven items that were partly derived from the items of Stank, Keller & Daugherty (2001). Financial performance is measured by five items that were partly derived from the items of "firm performance" in Narasimhan & Kim (2002).

Reliability is an assessment of the degree of consistency between multiple measurements of a variable (Hair *et al.*, 1998). The most commonly used measure of reliability is internal consistency. Flynn *et al.* (1990) suggested that the most accepted measure of a measure's internal consistency is Cronbach's alpha. The generally agreed lower limit for Cronbach's alpha is 0.50 to 0.60 (Flynn *et al.* 1990; Nunnally, 1994). Cronbach's Alpha tests were performed on the constructs. Since all alpha values are above 0.8, the items tested were deemed reliable. The data collected by surveys and other empirical designs is of little use unless its reliability and validity can be demonstrated (Flynn *et al.* 1990). There are two dimensions of construct validity: discriminant validity and convergent validity. Discriminant validity is the degree to which measures of different latent variables are unique (O'Leary-Kelly & Vokurka, 1998). Convergent validity relates to the degree to which multiple methods of measuring a variable provide the same results (O'Leary-Kelly & Vokurka, 1998). In our study, we try to assess the two types of validity by confirmatory factor analysis (CFA) in structural equation models. O'Leary-Kelly & Vokurka (1998) suggested that the CFA method of assessing convergent and discriminant validity is a more powerful tool and requires fewer assumptions than the traditional MTMM matrix method. At the beginning, we construct the CFA model using Lisrel program. In the model, each item is linked to its corresponding construct and the covariances among those constructs are freely estimated. The model fit indices are Chi-Square = 5197.43 with Degrees of Freedom = 1322, RMSEA=0.069, which indicate that the model is acceptable (Hu & Bentler, 1992). Generally, a construct with either loadings of indicators of at least 0.5, a significant t-value ( $t > 2.0$ ), or both, is considered to be convergent valid (Fornell & Larcker, 1981; Chau, 1997). For our model, all of the factor loadings are greater than 0.50 and the t-values are all greater than 2.0. Therefore, convergent validity is achieved in our study. In order to assess the discriminant validity, we build a constrained CFA model, in which the correlations among constructs are fixed to 1. This model will be compared with the original unconstrained model, in which the correlations among constructs are freely estimated. A significant difference of the Chi-square statistics between the fixed and unconstrained models indicates high discriminant validity (Fornell & Larcker, 1981; Chau 1997). In our study, the differences of chi-square are significant at

0.001 level. So, the discriminant validity is ensured.

#### 4.4 Structural Model and Hypotheses Testing

The structural model was analyzed based on the measurement models using the maximum likelihood estimation method. Table 1 shows the structural equation model and standardized coefficients. Eleven coefficients shown were significant at 0.05 levels. The initial model as shown in Figure 1 was tested, resulting in eleven significant path coefficients (H1-H9, H11-H12), suggesting the support in the data for the relationships. The data supported hypotheses H1-H9, and H11-H12, But hypothesis ten is not supported by the data. That means that supplier integration has no significant positive influence on SC performance. The results support the proposed structural equation model and the underlying theory except one hypothesis. The goodness of fitness indices for our model are  $\chi^2(1355) = 5900.35$ , NFI = 0.99, CFI = 0.99, RMSEA = 0.074, Standardized RMR = 0.015. These indices are better than the threshold values suggested by Hu & Bentler (1992). Therefore, our model can be accepted for future discussion.

**Table 1. Standardized path coefficients**

	Ctrus t	Stru st	Psic rc	Psis rc	Rcc	Rcs	li	Si	Ci	Scperf
Rcc	0.17		0.83							
Rcs		0.15		0.85						
Ci					0.64		0.36			
Si						0.35	0.62			
Scperf							0.11	-	0.88	
Fperf										0.96

“-” means insignificant path coefficient at 0.05 level.

#### 5. DISCUSSION AND MANAGERIAL IMPLICATIONS

The result of our hypothesis testing shows that a manufacturer's trust with the supplier (customer) has significant positive impact on the relationship commitment to the supplier (customer). That means that a company with a higher level of trust with customers/suppliers is more likely to have a stronger commitment to its relationships with its customers/suppliers. To enhance relationship commitment with its customer or supplier, the company can either select partners that it can trust or build the trust through proper management of the relationships. The existence of trust can help to reduce the perceived risks in the relationships and thus enhance the relationship commitment. Based on trust, commitment is formed to extend the relationships and trust often precedes the committed investment. This conclusion was also supported by some other researchers. Morgan & Hunt (1994) and Moore (1998) stated that trust and relationship commitment are salient and inter-related elements in structuring the inter-organizational interactions. Greyskens, Bernedict, Steenkamp & Scheer (1996) found that higher trust increases affective

commitment between to marketing channel members. The results of our study highlight the importance of trust between the manufacturer, its supplier and its customer.

The result of our study also indicates that perceived strategic importance of relationship with supplier or customer significantly impacted relationship commitment. That means that companies that perceive the greater strategic importance of developing and maintaining relationships with its supplier or customers are more likely to have a level of commitment with their supplier or customers. Many companies have considered strategic partnerships with its customer or supplier as strategic asset and have used this asset to gain competitive advantages in the market place. Some companies have developed customer relationship management (CRM) systems to help develop and maintain their relationships with their customers. Our findings indicate that companies will make strong commitment to the relationships with their partners when they consider such a relationship as of strategic important to them.

Relationship commitment is found to significantly impact SC external integration. That means that companies with a stronger relationship commitment to customers/suppliers are more likely to have a greater extent of customer/supplier integration. Since SC integration requires investment in time and other resources, the partners must have strong commitment in the relationship before they are willing to invest in SC integration activities. With a higher level of relationship commitment, the customers or the suppliers are more likely to cooperate with the manufacturer. So the manufacture will have less difficulty to integrate the customers or suppliers with its own operation process in the SC to achieve the competitive advantages.

This finding is partially supported by the results of several previous studies in different contexts. Morgan & Hunt, (1994) and Chen & Paulaj (2004) found that SC partners become integrated into their key customers' business processes and more tied to established goals with higher relationship commitment. Prahinski & Benton (2004) indicated that the buying firms should increase their efforts on cooperation and commitment in order to augment the supplier's commitment to ensure better supplier performance. However, no previous studies have investigated the impact of relationship commitment on the SCI. Our results indicate that a company needs to gain commitment to the relationship with its supplier or customers in order to achieve a higher degree of integrations with them. To achieve a higher level of commitment, the company must first recognize the strategic importance of relationship with its supplier or customer. Furthermore, the company must develop trust with its customers or the suppliers.

SC internal integration is found to have a positive influence on customer and supplier integrations. This means that companies with a greater extent of internal

integration are more likely to have a greater extent of integrations with its customer and supplier. The managerial implication of this finding is that the company needs to first integrate internal processes before it can effectively integrate with its customers and suppliers. This finding is different from what was found by Stank, Keller and Daugherty (2001). They suggested that collaboration with external SC entities increased internal collaboration, which in turn improves service performance. However in their study, they did not measure customer and supplier integration separately. Furthermore, the measurement items used in their internal and external collaborations do not capture all aspects of internal and external integrations. By using a more detailed list of measurement items, we are able to measure the different aspects of supply chain integrations. We believe that our findings are more logical. Internal integration is about the integration of the different internal functional departments, such as data integration, enterprise application integration, inventory management integration, periodic interdepartmental meeting, cross-functional teams, etc. The companies with a higher level internal integration can more effectively integrate their processes with the customers' or the suppliers' processes. If the companies have a bad internal integration, such as a low-level data integration, it is difficult for the companies to share or exchange information with their customers or suppliers. Without an integrative inventory management, a company will have little chance to share their production plans with the customers or suppliers. Therefore it makes more logical sense for a company to focus on internal integration first, then to integrate with the supplier and the customer.

The result of our study also indicate that both internal integration and customer integration significantly impacted SC performance, and SC performance has a positive influence on financial performance of the firm. It is interesting that supplier integration does not have a significant effect on SC performance. This might be because that manufactures in Mainland China and Hong Kong paid more attention to the customers. In order to get orders from the customers, manufacturers have to work hard to meet their requirements and respond to their requests quickly. Therefore, they are working hard to integrate their processes with the customers. As a result, customer integration contributed significantly to SC performance. For supplier integration, however, the manufacturer may not think that it is very important, and does not spend much resource to improve the inter-organizational processes with the supplier. They may just require the supplier to hold more inventories to buffer against uncertainty in the supply. This might be the major reason for the insignificant impact on the supplier integration on SC performance.

The relationship between SCI and performance has been discussed over a vast body of SC and operations literature. For example, Stank, Keller and Daugherty (2001) suggested that collaboration with SC partners

facilitates internal collaboration, which in turn enhances logistics performance. Frohlich & Westbrook (2001) demonstrated that SC companies with the widest degree of the arcs of integration achieve the highest level of performance improvement. Such previous researchers only tested the association between integration and SC performance. However, business executives may be concerned about both SC and financial performance. Our study also indicates that SC performance has a strong positive effect on financial performance. Therefore, manufacturer that want to improve financial performance needs to invest resources in both internal and customer integration to enhance the performance of the supply chain.

## 6. CONCLUSIONS

In this paper, we identified three types of integrations in supply chain and developed an instrument to measure SCI. We also investigated the relationships between the different types SCI, SC performance and the performance of the firm within the SC. Our result shows that internal integration positively influences supplier integration and customer integration. Furthermore, we found that customer integration and internal integration significantly influence SC performance and SC performance significantly influences the financial performance of the firm within the supply chain. However, supplier integration does not significantly influence SC performance. These findings enhance our understanding of how SCI influence performance and provide important guidelines for SC managers to enhance their financial performance through SCI.

In this study, we also investigated the impact of trust and relationship commitment on SCI. It was found that trust and perceived strategic importance of relationships with the customer and supplier significantly enhances relationship commitment with the supplier and customer. Relationship commitment, in turn, significantly improves SCI. Therefore, a company that wants to improve supply chain performance through SCI really needs to attach strategic importance to the relationship with the supplier and customer. Furthermore they must build trusting relationship with the customer and supplier.

This study is one of the first studies that examine the impact of trust and relationship commitment on SCI in from China. The findings from this study provide significant insights for practicing managers to enhance the performance of their supply chains. Furthermore, the models and instrument developed in this study can be used in future studies and thus this study also contributes greatly to the SCM literature.

# A Comparison of Brand Loyalty in Online and Physical Channels: An Empirical Application to Supermarkets

Javier Cebollada

Department of Management, Public University of Navarre, 31006 Pamplona, Spain,  
cebollada@unavarra.es

## ABSTRACT

In this study some differences in brand value in online channels are examined and compared with physical channels. The arguments presented lead to two hypotheses about brand loyalty in these environments. The first is that brand loyalty will be greater in online channels and the other that this difference is greater in product categories in which sensory factors predominate (those perceived by the senses, such as touch or smell). A choice model that depends on the degree of brand loyalty is proposed (Colombo and Morrison, 1989) and the hypotheses are contrasted empirically. Using data from 2003, the degree of brand loyalty and the degree of loyalty within a category are estimated for two product categories sold in an online and physical stores of one of the main Spanish supermarket chains.

**KEYWORDS:** brand loyalty, e-commerce, brand value, choice models, information availability and brand choice

## 1. INTRODUCTION

In this paper we propose to study some aspects of brand value in virtual or *online* commercial channels. Ever since the Internet began to be used for commercial purposes there has been a great deal of interest in ascertaining what differences exist between the online and traditional way of commercialising products. At first, many thought that the internet would cause an increase in competition that would lead to almost perfect competition, due to the increase in the size of markets, greater availability of information and the reduction in search costs for consumers. However, several studies soon showed that the Internet was a far from frictionless market. For instance, Brynjolfsson and Smith (2000a and 2000b) analysed prices of CDs and books in online and physical channels in purchases carried out using *shopbots* (web sites that compare prices of products in different online stores) and found that prices in the internet are often higher than those in physical stores, and that the most expensive internet stores were, at the same time, those with the greatest market share (e.g. Amazon). The explanation for these facts, according to the authors, is that consumers also use the brand as a sign of reliability and reputation and that considerable consumer loyalty exists on the Internet.

Subsequently, in various studies, the effect of brand and other marketing variables on consumer choice in the Internet have been studied. Degeratu et al (2000) compare consumer behaviour in an online store and a physical one. Using purchase data from a panel of consumers in several physical supermarkets and purchase data collected from an online supermarket's web site, the effect of brand, price and promotions are compared in the two environments for three product categories. In their analysis they include an interesting aspect that allows us to explain why the differences

found between the two environments depend on the product category: the role of the information available to the consumer in the brand choice process. The idea is that when sensory attributes predominate in a product category (attributes which are only perceived by the senses, such as smell or touch) the quality of information is lower in an online store and the effect of the brand is greater. On the other hand, when non-sensory attributes predominate in a product category (attributes which can be transmitted as information, for example the fat content of a margarine) the quality of information is higher in an online store and the effect of the brand is lower.

The role of information in consumer choice is an important aspect. In two articles by Alba et al (1997) and Burke et al (1992), it is seen that when consumers have less information (about the characteristics of a product) to take a decision, two things usually happen. Firstly, they grant importance to the brand (the brand, in these cases, plays a role which could be called the "halo effect" in the sense that it allows the value of the unknown attributes to be inferred). Secondly, consumers are much more likely to buy the same brand as on previous occasions, that is to say, they show greater brand loyalty. So, in situations of less information and more perceived risk, consumers minimise this by increasing loyalty. Generally, for the majority of product categories (at least those sold in supermarkets), it is more difficult to transmit information in an online store than in a physical store.

There are also other reasons for greater loyalty on the Internet. One is the fact that Internet consumers value highly the convenience and speed with which they can carry out their purchases (AIMC 2002), and so they are not willing to dedicate much time to these. One of the ways of simplifying and shortening the purchasing

process is to buy the same product as on previous occasions.

Another reason (closely related to the above) is the fact that tools exist on the Internet that allow the automatisation of purchases and may increase loyalty. In the case of online supermarkets, there are usually “personal lists” or “last shopping lists” that consumers can use in order to shop almost automatically, buying always the same products.

Therefore, in summary, our intention is to investigate two questions. Firstly, to see whether loyalty is greater in purchases carried out in online channels than in physical channels. As we have seen, there are sufficient arguments in favour of this position.

Secondly, we aim to verify whether, in product categories where sensory factors predominate, the difference in loyalty in online and physical channels is greater than in categories where sensory factors are less important. This, in a way, is equivalent to showing that when there is less information in the choice process, consumers are more loyal.

In order to examine both hypotheses concerning loyalty in online and physical environments, we will use a model that explains consumer behaviour as a choice problem between several discrete alternatives, and in which loyalty plays an important role. This is the Colombo and Morrison model (1989) which is described below.

We will subsequently carry out empirical analysis using purchase data from an online supermarket and a physical supermarket. We will estimate the parameters of the model for these data to see whether they support the aforementioned hypotheses. Finally, to conclude the paper, we will mention some of the study's principal limitations and some areas for future research.

## 2. A BRAND CHOICE MODEL WITH BRAND LOYALTY (COLOMBO AND MORRISON, 1989)

Let us take an individual who is faced with the choice of one alternative from a possible group of  $N$  (henceforth brands). Let  $A_1$  be his previous purchase and  $A_2$  his current purchase. The probability that his current purchase will be  $j$ , given that his previous purchase was  $i$  ( $i, j = 1, \dots, N$ ) is  $P(A_2=j/A_1=i) = P_{ij}$  so that

$$P_{ij} = \exp U_{ij} / \sum_{k=1}^N \exp U_{ik}, \quad i, j = 1, \dots, N \quad (1)$$

where  $U_{ij} = U(A_2=j/A_1=i)$ , is the utility of an individual currently purchasing  $j$  given that he previously bought  $i$ . Let us suppose that  $U_{ik} = U_k$  when  $i \neq k$ , that is, that the utility to the individual of the current purchase of a different product to the one bought previously is independent of this.

We define the “free” probability of purchasing  $i$  (without considering the previous purchase) as  $P(A_2=i) = \pi_i$ ,  $i = 1, \dots, N$ , where

$$\pi_i = \exp U_i / \sum_{k=1}^N \exp U_k, \quad i = 1, \dots, N \quad (2)$$

We now define  $\alpha_i$  ( $i = 1, \dots, N$ ) as

$$\alpha_i = (\exp U_{ii} - \exp U_i) / (\exp U_k + \exp U_{ii} - \exp U_i) \quad (3)$$

We should observe that  $\alpha$  may be considered as the degree of loyalty in brand  $i$  because it is monotonous in  $U_{ii} - U_i$ , that is, the greater the influence of having bought brand  $i$  previously on buying it now ( $U_{ii}$  is great), the greater are  $U_{ii} - U_i$ , and  $\exp U_{ii} - \exp U_i$ , and viceversa. If we suppose that the individuals who previously bought  $i$  can be grouped in two segments,  $A$  and  $B$ , where with  $U_{ii}^A = U_i$  y  $U_{ii}^B \rightarrow \infty$ , then we obtain  $\alpha_i^A = 0$  and  $\alpha_i^B = 1$ .

If we now apply the above expressions, we can now rewrite the probabilities  $P_{ii}$  and  $P_{ij}$  as

$$P_{ii} = \alpha_i + (1 - \alpha_i) \pi_i \quad (4)$$

$$P_{ij} = (1 - \alpha_i) \pi_j \quad (5)$$

We may consider the  $\alpha$  and  $\pi$  as the proportions of loyal and non-loyal customers to each brand.

On the other hand, if  $S_i$  is brand  $i$ 's market share,

estimated from the first purchase, then  $LP = \sum_{i=1}^N \alpha_i S_i$  is

the degree of loyalty in the market.

Estimation of the parameters  $\alpha$  and  $\pi$  is carried out using the maximum likelihood method.

## 3. EMPIRICAL ANALYSIS

### 3.1. Data

We are going to conduct an empirical application of the above model in order to verify whether it supports the two hypotheses mentioned in Section 1. We will use data from one of the five leading supermarket chains in Spain, present in a large part of the country, and a pioneer in Internet sales. For reasons of confidentiality, we will omit the name of the chain.

We will use data corresponding to purchases from June to November 2003 obtained at the point of sale in the physical supermarkets and at the web site of the online store, for consumers resident in several regions of the country, principally in large towns, which is where this distribution chain is established. Internet purchases are possible in practically the same towns as those in which physical supermarkets exist. The variety and depth of product lines are similar in both types of supermarket, as are the prices and the majority of promotions.

We will use data from two product categories (at a later date we intend to generalise the study using a larger number of categories): kitchen paper and domestic aluminium foil. The reason for choosing these categories is that for one of them, kitchen paper, sensory factors that are best appreciated in the physical supermarket, such as, texture, design, thickness, size etc. predominate. In the case of the aluminium foil, however, few of these sensory attributes exist: the packaging is opaque, and so one cannot see inside, and length in metres is a non-sensory factor that can be transmitted easily via Internet.

### 3.2. Transition matrices

These matrices reflect the number of consumers who have bought on a certain occasion one brand and another (or the same) the next time. Each element  $n_{ij}$  is the number of consumers who purchased brand  $i$  the first time and brand  $j$  the second. From these elements we can estimate the degrees of loyalty ( $\alpha$ ) in each brand as well as in the category as a whole (LP). Tables 1 and 2 show the transition matrices for both categories in both stores.

### 3.3. Results of the estimation

Table 3 shows the results of the estimation of the loyalty parameters for the brands ( $\alpha$ ) and within the product category (LP) in each store and for both product categories.

It can be seen that category loyalty is greater in both categories in the online store than in the physical one (0.80 compared to 0.41 in kitchen paper and 0.96 compared to 0.79 in aluminium foil). This confirms the first hypothesis that loyalty is greater in online stores than in their physical counterparts.

Furthermore, the difference between the two store types is greater for kitchen paper, which, as we have seen, is the category with most sensory factors that are

difficult to communicate to consumers in an online store. This result confirms the second hypothesis.

## 4. LIMITATIONS AND FUTURE RESEARCH

At present this research is ongoing, and so there are a number of limitations and aspects to be analysed.

One of the limitations is that we have analysed only two categories. In order to generalise the results we need to study a larger number of categories in which sensory and non-sensory factors clearly predominate.

It would also be interesting to analyse the role of prices and promotions. In the supermarket chain considered here these variables are similar, but they could produce different effects in the online store than in the physical one.

Another interesting aspect to analyse is how brand loyalty varies between brands, the model allows this to be done. For instance, we could compare private brands with leading brands (in the online store private brands enjoy the additional advantage of being able to be listed separately).

There may also be other factors in play apart from sensory and non-sensory attributes which can affect the transmission of information that influences consumer behaviour in both environments. For example, an interesting area to research is whether the differences between the two store types is due to the fact that they are used by different consumer types.

To conclude, in summary, we can state the following. We have analysed brand value through the degree of brand loyalty in online and physical stores and explained this in terms of the way information is transmitted in the two store types. We have related the presence of sensory factors with the online stores' difficulty in transmitting information. Finally, we have confirmed the two hypotheses put forward empirically.

## ABSTRACT

Customer retention is very important issue. In this reasons, many studies have been conducted for customer retention to demonstrate the potential of data mining through experiments and case studies. But current customer retention procedures only focus on detection of potential defectors based on likelihood of defection overlooking cost. In this paper, we propose an economic procedure for profit maximizing based on the customers' LTV and behavior state transition cost. For the aim of this paper, we use past and current customer behavior by integrating data mining techniques. In this procedure, SOM is used to determine the possible states of customer behavior from past behavior data. Based on this state representation, a Markov chain is applied to generate likelihood of state transition.

**Keywords:** *Customer relationship management, Data mining, Life-time value, Markov chain, Self-organizing map*

## 1. INTRODUCTION

Customer retention and life-time value(LTV) are an important issues in today's competitive environment. It is mapping customer data to define customer behaviors so that the processes of a company are fully occupied in acquiring, selling to, and maintaining a long-term relationship to a customer. The longer a customer stays with a company the more profit the customer generates. This is the outcome of a number of factors such as the higher initial costs of attracting new customer, the increase in the number of purchases, the long-term customer's better understanding of the company, and positive word-of-mouth. In this reasons, many studies have been conducted for customer retention to demonstrate the potential of data mining through experiments and case studies. But current customer retention procedures only focus on detection of potential defectors based on likelihood of defection overlooking cost.

This paper proposes an economic procedure for profit maximizing based on the customers' LTV and behavior state transition cost. For the aim of this paper, we use past and current customer behavior by integrating data mining techniques. Here, the term 'customer behavior' means action-oriented activities like calling, visiting Websites, and making purchases. However, predicting and understanding of customers' behavior for multiple periods is not easy because of the following reasons. First, customer defection cannot be predicted by only one behavior feature. Second, these features may also be related to customer defection in a highly nonlinear way. For this reasons, SOM(Self-Organizing Map) is used. In this procedure, SOM is used to determine the possible states of customer behavior from past behavior data. Because it facilitates the understanding of complex behavior dynamics so that several variables and their interactions can be inspected simultaneously. Based on

this state representation, a Markov chain is applied to generate likelihood of state transition. Also to maximize company's profit, the proposed procedure recommends the desirable behavior state for the next period based on the economic analysis of transition cost and LTV. The transition cost is based on the likelihood of state transition because that low likelihood is meant to be hard to recommend a desirable behavior state, if so we have to make more effort. Here, the term 'desirable behavior state' means that it has high LTV.

Based on the state representations, the following procedures are developed: (1) collecting behavior data and pre-processing, (2) determining the behavior states through SOM training, (3) determining a desirable state, (4) developing a marketing strategy for profit maximizing. We applied our procedures to the online game provider, because the histories of customer behavior are easily collected during multiple periods. Although our procedures are explained for a specific online game company, they can be applied to various service industries with fluent customer behavior data such as telecommunications, internet access services, and contents providing services. We begin by reviewing the previous study on defection detection in section 2 and the concept of SOM and Markov chain, which are prerequisites for our research, are summarized. In section 3, our suggested procedures are explained step by step. A case study is presented to illustrate and evaluate our procedures in section 4. Finally we summarize our contributions and outline areas for further research in section 5.

## 2. RELATED WORK

### 2.1 Existing Works In Customer Retention

Many Studies [2,5,6,7] have been conducted to detect potential defectors and preserve customer using data

mining techniques. Logit regression, decision trees and neural networks are the most frequently used technique to predict the likelihood of defection in these studies. However, these studies use static model to predict the likelihood of defection in spite of continuous and dynamic property of individual access behavior. Song et al. [7] and Kim et al. [5] proposed a solution that use static model to predict the likelihood of defection in spite of continuous and dynamic property of individual access behavior, but it also overlooked cost that is very important factor to make a decision. Compared to these existing works, our research builds an economic procedure for customer retention. Not only our procedure could predict potential defector, but also give the guidance to control whose undesirable behavior which leads to defection.

## 2.2 SOM

SOM was developed in its present form by Kohonen [4] and thus they are also known as Kohonen Maps. The SOM is able to map a structured, high-dimensional data onto a much lower-dimensional array of neurons in an orderly fashion. The mapping tends to preserve the topological relationships of the input data. Topological preserving means that the data points lying near each other in the input space will be mapped onto nearby map units. Due to this topology preserving property, the SOM is able to cluster input information and their relationships on the map. In this reasons we adopt SOM to determine every possible behavior state for a specific domain. The SOM has proven to be a valuable tool in data mining, full-text mining and financial data analysis. It has also been successfully applied in various engineering applications in pattern recognition, image analysis, process monitoring and fault diagnosis [8].

## 2.3 Markov Chain

A Markov chain, which is one special type of discrete-time stochastic process, can be used to predict the evolution of customer states [3].

A Markov chain has the following properties and assumptions:

? The probability distribution of the state  $i$  at time  $t \geq 1$  only depends on the state at time  $t$ .

? For all states  $i$  and  $j$ ,  $p(X_{t+1} = j | X_t = i)$  is independent of time  $t$ . These two assumptions can be specified by the conditional probabilities for a Markov chain:

$$p(X_{t+1} = j | X_t = i, X_{t-1} = i_{t-1}, K, X_1 = i_1, X_0 = i_0)$$

$$= p(X_{t+1} = j | X_t = i) = p_{ij}$$

$$\text{for all states } i_0, i_1, K, i_t, i, j$$

We adopted the probability distribution of the state  $i$  at time  $t \geq 1$ , and an absorbing Markov chain in which some of the states are absorbing and the rest are transient

ones. An absorbing state has a special transition probability,  $p_{ij} = 1$  [9].

## 3. PROPOSED PROCEDURE

### 3.1 Overall Procedure

In this section, we present the overall procedure of our methodology for defection detection and prevention with Figure 1. As shown in Figure 1, the proposed procedure consists of four steps. In the first step, all the behavior data related to defection is collected from operational databases and Web log files. In the next step, the SOM model is developed to determine all the possible behavior states which are mutually exclusive and exhaustive. The SOM is used to represent the state of each customer behavior from collected behavior data. After determining the behavior states using the SOM, all the continuous and complex behavior data is converted into discrete states. Based on this state representation, we determine a desirable state that is low defection rate, low transition cost, and high LTV. In the final step, we make a campaign plan to focus or modifying their behavior patterns for profit maximizing.

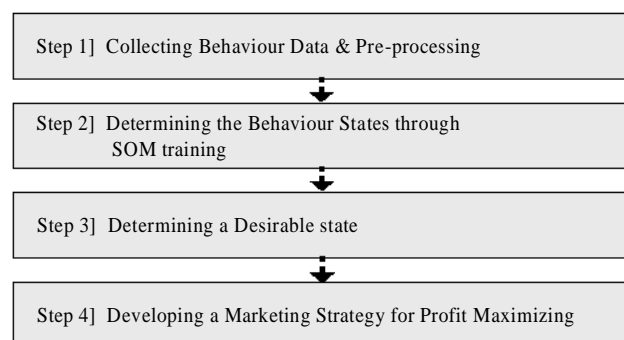

Figure 1. Overall procedure

### 3.2 Step 1: Collecting Behavior Data and Pre-processing

First of all, features that can affect defection are selected based on the prior knowledge of domain experts, and the value of features are collected over the multiple periods for each user from Web log files, purchasing databases, claim databases and the other sources. After collecting behavior data, data preparation is needed to build behavioral profiles. In particular the Web log data requires a great amount of effort to be transformed into usage data because of the difficulties in session identification and user identification. More detailed information for data preparation of the Web log can be found in Cooley et al.[1].

### 3.3 Step 2: Determining the Behavior States through SOM Training

Based on the selected input features, all the possible states of customer behavior are determined that are prerequisite for the SOM is a value array of the filtered

features such as the average length of session, the number of sessions in unit period, the number of congestions per unit period, and so on. In determining the behavior states using the SOM, the total number of states has to be given. If we set the total number of states to be very large, then the prediction model will lose the generalization capability because of overfitting. On the contrary, if we specify the total number of states to be very small, then the model may not have discrimination power between defectors and non-defectors. Therefore, choosing the number of states must be done carefully. The decision for determining the number of states is usually dependent on the characteristics of the domain and the goals of decision-makers.

Figure 2. Behavior states and their interpretations

The satisfactory number of states may be given by trial and error using past multiple periods' behaviour data and the target variable (i.e., whether they actually defect or not). To evaluate the performance of each number of states, FalsePositive and FalseNegative are used as a measure in our procedure. FalseNegative error is more important than FalsePositive error because FalseNegative is more costly and dangerous than FalsePositive. If a non-defector is incorrectly classified as a defector (i.e., FalsePositive), the customer will receive a large concession, but if a defector is incorrectly classified as a non-defector (i.e., FalseNegative), the customer will terminate services before a company reaches the customer and thus the company will lose revenue [2]. Figure 2 illustrates the possible behavior states which are the results of SOM learning. To interpret each state on the map, a decision tree analysis(C5.0) is additionally conducted.

### 3.4 Step 3: Determining a Desirable State

In this step, we determine a desirable state for the aim of this paper that is the longer a customer stays. For determining a desirable state, we find a lower defection rate state at first. And then, we estimate profit rate of each state and recommend maximum profit state.

#### 3.4.1 Average defection rate of each state

To determine a desirable state, at first, average defection rate have to be computed of each state :  $Df_i = D_i / N_i$

Where,  $Df_i$  : the average defection rate of the state  $i$   
 $D_i$  : the number of defection in the state  $i$   
 $N_i$  : the total number of state  $i$

#### 3.4.2 Transition cost using Markov chain

The transition cost is based on the likelihood of state transition because that low likelihood is meant to be hard to recommend a desirable behavior state, if so we have to make more effort. The likelihood of state transition is generated from making an absorbing Markov chain. To make an absorbing Markov chain, we have two assumptions. First, we assume that customer behavior states have the Markovian property. It implies that given the present state of the customer, the future probabilistic behavior of the customer is independent of its past history and only depends on the current state. This is because the customer's current state information most impacts the decision of the customer's next behavior. Second, we assume that all the customers can be potential defectors because they eventually leave the company some time or other if they are not continuously satisfied with the company's service in today's greatly compressed online game industry.

Table 1. The transition probability matrix

		State at time t+1					
		1	2	3	4	---	def
State at time t	1	0	0	0.2 9	0.1 4	---	0
	2	0	0.0 8	0.2 3	0.0 8	---	0.0 8
	---	---	---	---	---	---	---
	34	0	0	0	0	---	0
	35	0	0	0	0	---	0.0 9
def		0	0	0	0	---	1.0 0

To make a transition probability matrix, we used the states of all the customers for four periods (i.e., four weeks). We rearranged four pairs of transition data for each customer such as all of the transition data from t-4 week to t-3 week, from t-3 week to t-2 week, from t-2 week to t-1 week, and from t-1 week to t week (i.e., an absorbing state). And then we calculated transition cost,  $C_{ij}$ , based on a transition probability from state  $i$  to another state  $j$  as shown in Table 1.

#### 3.4.3 LTV generation using an absorbing Markov chain

In the Table 1, state 'def' means 'defector' which is an absorbing state. According to the property of an absorbing Markov chain, if the customer's current state begins in a non-absorbing state (i.e., from state 1 to state 35), then the customer will leave the non-absorbing state

and end up in one of the absorbing states (i.e., state 'def') eventually [9]. Figure 3 describes the general transition matrix for an absorbing Markov chain. It consists of four parts which are I, O, R and Q, as illustrated in Figure 3. We can find out the elapsed time to absorbing state 'def' in each non-absorbing state by using the matrix  $(I - Q)^{-1}R$ .

Figure 3. The transition matrix for elapsed time

Table 2 describes the outcome of the matrix  $(I - Q)^{-1}R$ . In this Table, we can see that if a customer belongs to state 1 at time  $t$ , then the customer will defect 11.5 periods later on average. The elapsed time to absorbing state 'def' can be used as LTV generation. We use simple LTV that only considered period (i.e., elapsed time) and profit (i.e., fee about session time):  $LTV_i = E_i \cdot P_i$

Where,  $E_i$  : the elapsed time of the state  $i$

$P_i$  : the average profit of the state  $i$

Table 2. Sample of the elapsed time to an absorbing state

State	Elapsed time (Week)	State	Elapsed time (Week)
1	11.5	6	14.1
2	9.8	7	12.9
3	7.5	8	9.4
4	11.3	9	10.5
5	8.2	10	12.2

### 3.4.4 Recommend a desirable state

In this step, we estimate gain of each state and recommend a desirable state that is maximum profit state. As it mentioned, we find a desirable state using a defection rate, and then desirable state is determined based on the profit that is transition cost and the LTV.:

$$Gain_{ij} = (LTV_j - LTV_i) / C$$

### 3.2 Step 4: Developing a Marketing Strategy

For the defection prevention, we will design segmental campaigns based on the information of a To-Be state.

Figure 4. Segmental campaign design

Figure 4 provides samples of the campaign design. An As-Is behavior state and a To-Be behavior state for two segments are presented in this figure. From this figure, the campaign design for '4' should focus on reduction error, and for '12' should focus on extending session length. We will illustrate a case of campaign design in section 4.

## 4. A CASE STUDY

### 4.1 Data

The dataset for the case study is prepared from an online game provider in Korea. We sampled 255 customers and collected totally 114,736 transactions for those customers from various sources such as web log data and the transaction database. The collected input data for defection prediction contain the total session length for a week, the total number of sessions for a week, the total number of access errors caused by congestion, and the average length per session. Customer profiles were maintained for the four input features during four consecutive weeks for each customer with an actual defection indicator. We defined a defector as the customer who has no session time for one month, because there is no voluntary sign of withdrawal in this Internet game site.

### 4.2 Determining the Behavior States

As it mentioned, FalseNegative error is more important than FalsePositive error because if a non-defector is incorrectly classified as a defector (i.e., FalsePositive), the customer will receive a large concession, but if a defector is incorrectly classified as a non-defector (i.e., FalseNegative), the customer will terminate services

before a company reaches the customer and thus the company will lose revenue. Therefore, we made an experiment on several cases and select a minimum of FalsePositive error in FalseNegative error is limited to 5%. The outcome is described in Table 3 and '5 □7' matrix, FalsePositive error is 17.6% and FalseNegative error is 4.6%, is appropriate to our case.

Table 3. FalsePositive and FalseNegative error matrix

Actual Predicted	6 □6		5 □7		7 □5	
	Def	Non	Def	Non	Def	Non
Defector	-	11.7	-	17.6	-	15.5
Non-defector	11.9	-	4.6	-	6.9	-

#### 4.3 Determining a Desirable State

For determining a desirable state, we programmed a profit generation automatically using a Visual Basic 6.0. Table 4 provides desirable states(i.e., to-be) as a result and differences between as-is and to-be.

Table 4. Differences between as-is and to-be

As-is	To-be	Differences between as-is and to-be
1	2	Increase in session number
2	3	
3	10	
4	10	Increase in average session time
16	24	
17	18	
18	25	
9	10	
10	18	Increase in session time
11	12	
13	12	
22	25	
23	24	Increase in session number and time
12	25	
19	18	
21	25	Decrease congestion number
24	25	
27	25	Increase in session number and decrease congestion number
29	23	
32	24	

#### 4.4 Developing a Marketing Strategy

Table 5 is a real cases and gives some idea about campaign object and feasible campaign based on Table 4. For instance, if we want to induce a customer in state '1' to desirable state '2', then we should focus on extending session number. And in this object, we can make a campaign plan like Table 5.

Table 5. Sample of the feasible campaign

Object	Feasible campaign
Extending session time	- Providing additional free access time - Providing gifts and awarding prizes based on the accumulation point
Extending session number	- To provide free coupon - Recommend new game information - Frequent update of the site and make an event
Reducing congestions	- Recommending the use of non-peak time by suggesting a discount rate - Sending a manual for congestion

#### 4.5 Evaluation

In this section, we compare the prediction accuracy of the proposed procedure to that of the MLP neural network and a decision tree. To evaluate the performance of our defection detection procedure, we use FalsePositive and FalseNegative as measures. Figure 5 shows the comparative results of prediction accuracy among our suggested model and the MLP neural network(MLP NN) based on same input data in our domain(online game provider). Our proposed procedure resulted in both a slightly higher recall and hit ratio. This means that our proposed procedure can cover defection prevention as well as defection detection without deterioration of prediction accuracy compared to that of the MLP neural network.

Figure 5. Comparative results of prediction accuracy

#### 6. CONCLUSION

We proposed an economic procedure for profit maximizing based on the customers' LTV and behavior state transition cost. For this purpose, possible states of customer behavior are determined from past behavior data using SOM. Based on this state representation, the transition cost and LTV can be predicted using a Markov chain. In addition, our proposed procedure is extended to defection prevention for potential defectors and it assists in building segmental campaign plans by recommending the desirable behavior state for the next period to lower

the likelihood of defection. Our proposed approach is a practical implementation procedure of eCRM because it tries to maintain a relationship with potential customers using an automated campaign procedure continuously

As an area for further research, we have a plan to develop a system for defection detection and prevention based on our suggested procedure. In this study, we applied our procedure to the online game provider, but we believe that it can be applied to other service industries such as telecommunications, Internet access services, and contents providing services, and check the effectiveness of our proposed procedure.

# A Global Comparative Study of Online Auction Markets

James K. Ho

Liautaud Graduate School of Business, University of Illinois at Chicago, IL 60607, USA

jimho@uic.edu

## ABSTRACT

Online auctions have demonstrated how e-commerce can transform business, and not merely transplanting conventional processes to a new medium. The resulting emergence and growth of diverse markets pose the intriguing question of what 'shape' a given market is in at a particular moment of development. The approach of Topological Analysis, which is based on the Star Plot method in data visualization, provides such a model using only operational data, without any expert knowledge of the specific auction market, or financial details from the transactions. Using extensive analysis of data available on eBay.com, the foremost online auction platform to date, a global comparative study of four markets in eight countries is conducted. The results shed light on the evolution of electronic markets, as well as their regional and cultural variations.

**Keywords:** online auctions, market topology, data mining, data visualization

## 1. DATA VISUALIZATION AND THE SHAPE OF ONLINE AUCTION MARKETS

The Internet is a new medium of communication connecting potential partners in e-business worldwide. The initial frenzy over its promises led to grossly exaggerated valuations of business models that were mere transplantations of existing processes to the alternative channel. Now that the bubble has burst [8], more sensible and critical thoughts can be turned to true transformations that are creating and nurturing markets of the future, and shaping business strategies in a networked world. Online auction is one of the very few cases that has held a steady course ([5], [6], [7], [10]), as evidenced in the success to date of eBay.com. Founded in September 1995, eBay has become a global trading platform where on any given day, there are more than 16 million items listed across 27,000 categories. In 2003, at least 30 million people will buy and sell well over \$20 billion in merchandise, so that the entire culture it engenders is now being described as the eBay economy [3]. It is also the richest source of data for online auction markets, as records of all its transactions are available to the public (on a 2-week rolling basis). In (Ho 2004) the intriguing question of what 'shape' a given market is in at a particular moment of development was posed. Using the Star Plot method of high-dimensional data visualization [4], a topological model was developed, based only on operational data, without any expert knowledge of the specific auction market, or financial details from the transactions. The dimensions in this model are reviewed in the next section. Applications of this Topological Analysis include the study of market evolution over time, market design and simulation in experimental economics, as well as inter-brand or international comparative studies of online auction markets. As a full-scaled example of the latter, the results for four markets (digital cameras, classical CDs, diamond rings, Star Wars play-figures) in eight countries/regions (US, Canada, Australia, United Kingdom, France, Italy, Spain, Taiwan) are presented.

## 2. TOPOLOGICAL ANALYSIS OF ONLINE AUCTION MARKETS

In [2], a topological model for an online auction market is defined to be a simultaneous graphical display of all the dimensions of its relevant data base, which provides a geometrical shape as a descriptive, visual statistics of the market. In particular, various dimensions were identified from available data for constructing a specific topological model that can help discern market efficiency. Such a model provides a visual cue for whether a market is favorable to buyers or sellers, without expert knowledge of the items involved or the prices attained. The dimensions in this model are briefly reviewed below.

### *Gross Activity*

The absolute size of a market is indicated by the average number of auctions being offered per day.

### *Net Activity*

As a categorical measure of the effective activity in an auction market, the proportion of listings that ended with at least one bid is used. In cases where a reserve price is in effect, the listing is counted whether the reserve is eventually met or not.

### *Participation*

For those auctions that resulted in at least one bid, an aggregate measure of activity is the average number of bids. Multiple regular bids from the same buyer are counted separately.

### *Seller Diversity*

For a sense of whether a market is dominated by relatively few sellers, or there is diverse sources of supply, the number of auctions in the data collection offered by each individual seller is tracked and the distribution is used as an indicator of seller diversity

### *Seller Experience*

At the completion of any auction on eBay, the buyer and seller have the opportunity to post feedback to the system. The net feedback rating is used as a surrogate measure of an eBay's experience. The distribution of four levels of seller experience—from 'Beginners' to 'Veterans' is compiled for each market.

### *Buyer Diversity*

For a sense of the distribution of buyer participation over the auctions in the data set, the number of auctions in which each user placed a bid is tracked. Typically, each identified user participated only in a small percentage of the total number of auctions. Therefore the absolute number, rather than the percentage, is used. Again, four ranges are arbitrarily chosen: [1], [2 – 5], [6 – 10], [ $>10$ ]. The proportions of buyers falling within these ranges are recorded.

### *Buyer Experience*

This is completely analogous to the measure of seller experience. The feedback ratings of buyers identified in the data set are classified into the same four categories, and the proportions of buyers at each level are compiled for each market.

### *Matching*

Since the intent of auction markets is for competing bidders to arrive at a fair value for the item offered, an auction that ended with a single, winning bid does not make for an interesting or typical case. However, it does signal a unique match in supply and demand.

### *Dueling*

In contrast to single-bid matching, dueling is an indication of keen competition. While the actual dynamics of such bidding patterns, in terms of who is challenging and who is responding, can get quite complex and combinatorial, a tractable criterion can be defined for the occurrence of 'dueling' between two preeminent bidders. Dueling is recognized when the two bidders with the highest number of bids together account for the majority (or some other pre-set level) of the bids, provided the total number of bids exceeds some pre-set threshold (6 is used throughout this study). The last provision is to exclude trivial cases, for example when there are only two bidders with one bid each. Note that the two most active bidders may not actually have encouraged in head-to-head dueling, and neither of them needs to be the eventual winner.

### *Stashing*

In markets for items whose value will increase with scarcity, such as collectibles, certain buyers may set out—to whatever extent—to 'corner' the market. They hope to build up a stock and profit from higher valuations in the future. Or there may be professional dealers with brick-and-mortar sales outlets who have managed to arbitrage actual price differentials between eBay and the conventional marketplace. In either case,

'stashing' activities would be reflected in frequent purchases of the same or similar items within the time frame of the dataset by such buyers. As an indicator of stashing, the highest percentage of the auctions in the dataset won by any single buyer is used.

### *Sniping*

The specific design of online auction will affect the participants' behavior, and hence the topological shape of the market. Three parameters for the eBay online auction system (second price, fixed deadline, and public) lead to an interesting and significant phenomenon known as "sniping" [9]. This is the strategy of placing a first bid at the very end of the auction. In this work, we consider an auction to be won by sniping if the winning bid was placed within one minute from termination, and it was the first and only bid placed by the bidder.

### *Retailing*

On eBay, sellers are provided with an option to offer the item at a fixed price. This is known as Buy-It-Now (BIN). While this option clearly detracts from the true spirit of online auctions, its viability is certainly self-regulating, and its effectiveness affords us another glimpse of the shape of the market.

### *Proxy*

On eBay, a user can submit a maximum bid of what he or she is willing to pay for the item. Then, as necessary, the system will place the appropriate incremental bid for the user against other incoming bids, until the maximum is reached. Auctions won by proxy bids are indicated by winning bids that are not the last ones placed chronologically.

## **3. A BUYER-SELLER DICHOTOMY FOR ONLINE AUCTION MARKETS**

Our topological model is based on the star plot for displaying multivariate data with an arbitrary number of dimensions [1]. Each data point is represented as a star-shaped figure (or glyph) with one ray for each dimension. As the resulting shapes depend on the configuration of the dimensions, we further analyze the observations along the dimensions identified above in an effort to present a visual model (see a generic example in Figure 1) of the shape of online auction markets. This is done by partitioning the dimensions into a buyer-seller dichotomy.

Gross and net activities are significant for inter-market comparisons, and neutral to buyers and sellers. We map gross activities, on some relative scale for all online auction markets, on the upper vertical axis, and use it as the radius of a circle to frame the visual model. Net activities, as percentage of auctions with bids, are mapped on the same vertical axis. Participation, expressed as the average numbers of bids per auctions, is mapped on the lower vertical axis. This way, the size of the circle represents the size of the market relative to

all others, whereas the span between the net activity and participation indicates its vibrancy.

Figure 1. Topology of Online Auction Market

### 3.1 Buyer dimensions

The seller profiles, in terms of diversity and experience, are buyer dimensions. For diversity, we make the assumption that dominance in market share by relatively few sellers does not provide as much sourcing opportunities for buyers as when there are more different sellers. Analysis of data from over thirty markets led us to propose the use of the proportion of sellers offering 1 per cent or less of the auctions as the metric for diversity. For experience among sellers, the rationale is that an even distribution is favorable to buyers. The skewness of any observed distribution can then be normalized against the even distribution, which is top of the scale. In particular, the maximum of  $0.25^4$  which equals 0.0039 is normalized to 1.0 so that a distribution of, say, (0.4, 0.3, 0.2, 0.1) will be normalized to 0.61 on this scale. The two seller profile dimensions are mapped radially in the top-right quadrant in Figure 1.

Single-bid matching, though not an indicator of the vitality of a true auction market, does work in the favor of buyers. It meets their demand at opening bid prices, which are likely to be bargains. The success of winning bids by sniping also put buyers at an advantage. As demonstrated in [9], the winning bid prices can be expected to be undervalued. Buy-It-Now options, if acceptable to buyers, necessarily reflect favorable prices, and so can be ruled a buyer dimension. These three buyer dimensions, all expressed as percentage of total auctions, are mapped in the lower right quadrant in Figure 1.

### 3.2 Seller Dimensions

The buyer profiles, in terms of diversity and experience, are seller dimensions. Analogues to the buyer dimensions we make the assumption that diversity in participation and an even distribution in experience

among buyers are favorable to sellers. For diversity, we use the proportion of buyers participating in a single auction as the metric. For experience, the skewness of the distribution is normalized against the even distribution as described above. These two dimensions are mapped in the top right quadrant in Figure 1.

Dueling, which signals competitive bidding to raise the winning price is obviously to the advantage of sellers. Stashing by buyers with ulterior motives, which are not necessarily rational in the actual market, is also a seller dimension. Finally, proxy bidding can both attract bidders who would otherwise be too busy to monitor an auction, as well as elicit true valuations from potential buyers to help maximize the final price, and hence a seller dimension. These three seller dimensions, all expressed as percentage of total auctions, are mapped in the lower left quadrant in Figure 1.

## 4. A GLOBAL COMPARATIVE STUDY

The graphical display of the topological model of online auction markets provides a visual aid in describing the 'shape' of a market at any particularly stage of its development. The dimensions (or attributes) deemed advantageous to buyers and sellers are mapped on the right and left sides of a circle, respectively. With proper normalization and harmonization of the scales, the relative areas of the two sides of the star glyph provide a visual cue to market efficiency: a larger right side favors buyers, and vice versa. By themselves, such snapshots encapsulate market characteristics, especially when large numbers of markets are to be studied. As a full-scaled example, a global comparative study is conducted.

### 4.1 The Countries/Regions

By August 2004, eBay has expanded globally to 23 country/region-specific sites along with its main, US-focused home site. Some of these operate on the same technical platform as the main site. Others, being partnerships or "buy-outs" of local ventures, typically in Latin America and Asia, do not. To date, only sizable sites using the home platform offer recent historical data on completed auctions on an approximately two-week rolling basis. After eliminating sites where activities are not yet high enough to provide any significant data collection, eight are chosen: United States (US), Canada (CA), Australia (AU), United Kingdom (UK), France (FR), Italy (IT), Spain (ES), and Taiwan (TW).

As further evidence of how e-business blurs conventional geo-political distinctions, the scope of the auction markets under any country-specific site is not strictly defined. In general, they offer listings in the local language submitted to the local site, from sellers with items that are located within the specific country. However, it is a seller's option whether to deliver outside of the country or region, and there is no

restriction on where a seller can post a listing. For instance, we might find a German supplier of musical CDs listing offers on, say, the Taiwan site. Ultimately, the relative scope of various markets will be determined by market forces in the form of shipping costs, ease of payment, and language preferences.

## 4.2 The Markets

Since eBay provides over 27,000 categories of auction items, it may seem trivial to define a market a priori, e.g. digital cameras, and expect to collect data for such a specific item. Actually, the underlying database is keyword driven so that substantial cross-listing can result for items which may only be remotely related. Even with progressively refined drilling to filter extraneous selections, it is impossible, short of item by item scrutiny, to ascertain exact pertinence of the collected data to the prescribed market. For example, even if the search for digital cameras were restricted to a specific brand and model, it would still fail to preclude accessory items such as carrying cases. If a filter is used to block out carrying cases, then it may exclude cameras with carrying cases. With this in mind, the choice of markets for this study is made in part to minimize such fuzziness, as well as to contrast items with common versus subjective values, practical use versus amusement, technology versus craftsmanship. Moreover, they have to be sufficiently active on most of the chosen sites to provide significant data. Even with these criteria, the options are enormous and the decision is arbitrary.

### *Digital Cameras:*

To sharpen the market focus, models with medium pixel capacity is specified. On most sites, these are classified under 3.0–4.0 Megapixels. For ES and UK, 2.1–4.0 is used; 3.1 and over for FR. No subcategory is available for TW.

### *Diamond Rings:*

These are under the category of “Jewelry & Watches” on all sites. While a specific subcategory is available on some sites, a keyword search on “Diamond” may be necessary under “Rings” on others.

### *CDs Classical:*

These are listed under the category of “Music” or “Music and Instruments” and the subcategory of “CD” and genre of “Classical”.

### *Star Wars Toys and Games:*

These are mostly so-called action figures, memorabilia, and collectibles engendered by the Star Wars movies, under the “Toys and Games” category.

## 4.3 The Data Samples

As we intend to study auction markets at particular points in their development, the time span for the collected data should not be too long. However, to

ensure accurate representation of the actual dynamics of the markets, enough data points should be included. From both logistical and statistical considerations, we chose a target size of 500 auctions over a period of from one to three weeks, in June and July 2004. Note that these are not random samples, but complete records taken over a contiguous interval of time. Not all the actual markets can support this sample size within the given time frame. In those cases, the size is limited to data availability. The sample sizes for this study are summarized in Table 1.

Table 1. Sample size of datasets

Sample Size	US	AU	CA	UK	FR	IT	ES	TW
<i>Digicam</i>	500	444	495	498	100	152	151	426
<i>Diamond Ring</i>	543	504	501	337	98	22	8	10
<i>CDs Classical</i>	501	301	402	500	159	66	-	36
<i>Star Wars</i>	500	587	502	506	602	13	174	20

## 4.4 The Results

The bidding history for completed auctions on the eBay sites are copied and stored in MS Excel spreadsheets. Macro programs are designed to perform the data mining and compile statistics for the dimensions in the topological model. To render meaning to the visual cue for the buyer-seller dichotomy, the statistics are normalized and harmonized by a transformation that maps (approximately) the first, second, and third quartiles for the entire collection of datasets on each dimension to the unit-free scale of [0.25, 0.5, 0.75], respectively on the unit interval. This way, we can visualize the relative advantages to buyers and sellers without knowledge of the economic details of the transactions.

The results for our datasets are presented by market in Figures 2-5. Since the primary purpose of this work is to illustrate the topological model as a data visualization tool, we will observe, compare, and discuss market characteristics from this perspective, rather than dwelling on the quantitative or statistical analysis. First we note that in terms of net activity (average number of auctions with bids per day), the US site dominates by orders of magnitude. This is indicated in the bar-chart at the center of each of Figures 2-5.

Markets do exhibit their characteristic shapes. As the US site is most developed, the shapes of the markets there provide useful frames of reference. Digicam has an “upright” shape. Diamond Ring is slanted, from top-left to bottom-right. CDs Classical suggests a shamrock leave. Star Wars is more spade like. For a given market, the resemblance across international sites can still be discernable. Significant variations may be attributed to operational factors, regional or cultural differences, but even more likely to market size and stage of development. For example, the Buy-It-Now option tends to be practicable only for large enough

markets. The one remarkable operational factor concerns the TW site. In its promotional period, which covered the data in this study, all listing and commission fees were waived. As a result, the ratio of total listings to those with bids was extremely high. This effect is likely to vanish as soon as regular fees are charged.

In terms of the buyer-seller dichotomy, there is no clear advantage for each side except for Star Wars, which appears to favor sellers in the larger markets. For the others, we can comment on the relative conditions of the markets just by examining the topological plots. Shoppers of digital cameras should find eBay auctions a reasonable source of supply. The only shortcoming based on our model seems to be a dominance of experienced sellers. For hi-tech new products, this is hardly a concern. For sellers in this market, conditions are good as well. The lack of stashing is no surprise for items that are neither collectible nor expected to gain in value. The viability of markets such as Diamond Ring, which involve high value items that are difficult to evaluate online, attests to the potential of e-business. For buyers, the high level of matching translates to opportunities for finding a ring to one's liking at a relatively low starting bid price. With CDs of classical music, it is essentially a retail market as there is scant competitive bidding. Yet the market is viable for specialized and experienced sellers who hope to profit from volume in spite of low margins.

## 5. CONCLUSION

We presented a global comparative study of four online auction markets in eight countries as a demonstration of a topological model as a data mining and visualization tool, relying only on operational data. A graphical rendition of the model gives shape to such markets, facilitating the visualization of characteristics such as market efficiency, and changes that may favor either buyers or sellers. Conceptually, the star glyph maps market topology into iconography. Research is ongoing to quantify this approach by optimising the dimensional configuration to maximize the resolution of the buyer-seller dichotomy. While the topology is completely independent of market economics, information on the latter can be used in either a knowledge-base or neural net approach to identify shapes of interest. While only casual observations are made for the present purpose of illustration, the

potential exists for more in-depth analysis in the context of plotting e-business strategies in a networked economy, especially when the online auctioning model becomes more widespread in a business-to-business (B2B) environment.

## ACKNOWLEDGEMENT

Santosh Bukitgar designed the MS Excel macros for the data mining used in this work. The EMBA class in e-Commerce Projects at UIC in Summer 2004, contributed to the data collection and analysis in this study.

## A Model of Customer Lifetime Value Consider with Word-of-mouth Marketing Value

Yongmei Liu, Zhenjun Zhao, Yanlong Zhang, Hongjian Lu

Business School, Central South University, Changsha, Hunan 410083, China  
ymliu@mail.csu.edu.cn

### ABSTRACT

With the rapid development of IT technology and fierce competition of market, the customer relationship management(CRM) has gained its importance in the market. Companies have attached importance to acquiring and retaining the most profitable customers. So calculating customer's value is a significant segment for every effective CRM. Many researches have been performed to calculate customer's value based on customer lifetime value (LTV). But, these calculations can't effectively include the whole customer value, especially for the word-of-mouth marketing value. This paper proposes a new LTV model which considers the customer's past profit contribution, potential value and word-of-mouth marketing value, and gives a more reasonable LTV value in CRM for the company to make a decision.

**Keywords:** Customer Relationship Management, Customer Lifetime Value, Word-of-Mouth Marketing Value

### 1. INTRODUCTION

Customer Relation Management (CRM) is a strategy used to comprehend and influence customers' behaviors through effective communication in order to improve the customers' acquisition, retention and loyalty and achieve profitable growth ultimately <sup>[1]</sup>. One hot topic in CRM research is how to measure customer value, as the accurately calculating of customer value is the groundwork of identifying and classifying target customers effectively, and it is also the key factors of success of CRM. Customer value is studied through customer equity, customer profitability and lifetime value. In this paper we consider the customer values as the total benefit for corporation during customers' lifetime, namely, LTV—Customer Lifetime Value <sup>[2]</sup>. There are already several definitions of LTV, we take Frederick Newell's <sup>[3]</sup> here and amend it as:

LTV is, which follows along with the time continuing, the revenues gained from the customers (individual, family or middleman) after the deduction of the total cost of attracting, selling, and servicing customers, and discounted to the present.

It was generally accepted that customer value comprises customers' present value, potential value and loyalty, but we do think the value of world-of-mouth communication is an important component of customer value. Corporations can be benefited as customers recommend productions or services to their friends or family members through world-of-mouth communication way, considering that customers depend more on informal information sources such as acquaintances during decision-making of purchasing <sup>[4-5]</sup>. According to a tailed survey to retailing conducted by a Japanese investigating company, 80% saleroom is from present customers, and 60% new customers are from commendations of present customers <sup>[3]</sup>. Google is a good example: it holds a great deal of users with few commercial advertisements <sup>[6]</sup>, showing the effectiveness of world-of-mouth communication. Therefore, considers the customer value from four aspects includes current value, potential value, customer loyalty and communication value would be better to indicate the true connotation of LTV.

So, based on the Hyunseok Hwang's conceptual framework of CRM <sup>[7]</sup>, a CRM conceptual framework based on LTV is shown in Fig.1.

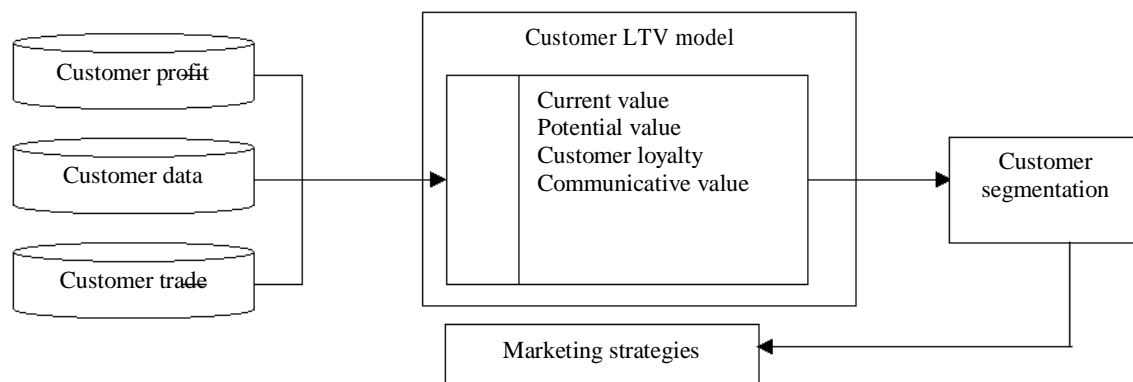

Fig.1. CRM framework based on LTV

Fig. 1 reflects main flow of CRM and the important roles of customer value composing and measure in CRM. Although the measure of LTV is a key factor of CRM, but most corporations haven't got LTV data so far. One important reason of this situation is the complexity of factors, which can influence calculating of LTV. This paper reviewed past LTV models and analyzed factors which influence LTV, proposed a new LTV model considers the customer's past profit contribution, potential value and word-of-mouth marketing. This model can give a more reasonable LTV value in CRM for the company to make a decision, and provide an academic foundation for corporations to manage customer relation better.

## 2. RELATED RESEARCHES ABOUT LTV

There are a lot of researches on calculating customer value, some researches, such as Huang Yixiao, try to establish an evaluation system by using neural network [8], but most researchers follow Frederick FR.'s net present value (NPV) evaluation system [3]. However most LTV models based on NPV evaluation system exist various limitations, it's difficult for them to reflect the true customer value. The basic LTV model [9] formed based on revenues of loyal customers as follows:

$$LTV = \frac{\ln \left[ 1 - \frac{1}{(1+r)^n} \right]}{r} \quad (1)$$

Where  $\ln$  are revenues that the corporation gain from the loyal customers,  $r$  is interest rate,  $n$  is the number of years that the customer is loyalty for the corporation. The virtue of the model is its simple calculation, and the disadvantage is that it based on the future revenues' calculation. The measure didn't consider the cost and tend to lead LTV to crossroad.

Considering this situation, Berger and Nasr (1998) have proposed LTV calculation model [7], which reflect the fluctuation of sales and costs.

$$LTV = \sum_{i=0}^n \pi(t) \times \frac{1}{(1+r)^i} \quad (2)$$

Where  $i$  is the period of cash flow customer transactions,  $n$  is total number of periods of projected life of the customer under consideration, and  $r$  is interest rate,  $\pi(t)$  is the function of customer profits according to time  $t$ . Formulating precise  $\pi(t)$  is the most important factor in calculating LTV precisely. LTV models evaluate the long-term value of customers focused on the entire lifetime of customers, however, the long-term value does not fit for the industry having stiff competitions and rapid changes of market environments, the wireless communication industry is good example, which are very sensitive to the external environments and the customer defections. Customer defection is also a critical issue of LTV model because it affects the length of service period and the future profit generation.

Therefore, Hyunseok Hwang suggest a LTV model considering churn rate [7].

LTV<sub>i</sub> =

$$\sum_{t_i=0}^{N_i} \pi_p(t_i) (1+r)^{N_i-t_i} + \sum_{t_i=N_i+1}^{N_i+E(i)+1} \frac{\pi_f(t_i) + B(t_i)}{(1+r)^{t_i-N_i}} \quad (3)$$

$t_i$ : service period index of customer  $i$

$N_i$ : total service period of customer  $i$

$r$ : interest rate

$E(i)$ : expected service period of customer  $i$

$\pi_p(t_i)$ : past profit contribution of customer  $i$  at period  $t_i$

$\pi_f(t_i)$ : future profit contribution of customer  $i$  at period  $t_i$

$B(t_i)$ : potential benefit from customer  $i$  at period  $t_i$

This model ignored the importance word-of-mouth marketing value from customers, especially in cybereconomy era, so it is also limitation for calculating the customer's value.

## 3. A MODEL OF LTV CONSIDERED THE WORD-OF-MOUTH MARKETING VALUE

### 3.1 A New LTV Model

The word-of-mouth communication has been concerned by people, for the word-of-mouth communication can increase corporations' profits by attracting the new customer for corporations. Suppose the customer  $i$  has a little profit for a corporation, but he (she) can attract many more profitable customers for the corporation by word-of-mouth communication. So the customer  $i$  should have high customer value. However the models above can't consider this situation, and therefore we propose a model as follows:

$$LTV_i = \sum_{t_i=0}^{N_i} \pi_p(t_i) (1+r)^{N_i-t_i} + \sum_{t_i=0}^{N_i} S_p(t_i) (1+r)^{N_i-t_i} + \sum_{t_i=N_i+1}^{N_i+E(i)+1} \frac{\pi_f(t_i) + B(t_i)}{(1+r)^{t_i-N_i}} + \sum_{t_i=N_i+1}^{N_i+E(i)+1} \frac{S_f(t_i)}{(1+r)^{t_i-N_i}} \quad (4)$$

Compare with Eq.(3), Eq.(4) adds two parts

$$\sum_{t_i=0}^{N_i} S_p(t_i) (1+r)^{N_i-t_i} \quad \text{and} \quad \sum_{t_i=N_i+1}^{N_i+E(i)+1} \frac{S_f(t_i)}{(1+r)^{t_i-N_i}},$$

they denote the net present value(NPV) of customer's past word-of-mouth communication and the future word-of-mouth communication respectively, where  $S_p(t_i)$  is past word-of-mouth communication value of customer at period  $t_i$ , and  $S_f(t_i)$  is future word-of-mouth communication value of customer at period  $t_i$ .

### 3.2 Calculating $S_p(t_i)$ And $S_f(t_i)$

In order to calculate the customer's word-of-mouth marketing value, we divide it into direct and indirect word-of-mouth marketing value. Suppose there is a customer  $i$ , then we define direct word-of-mouth marketing value  $S_0$  as a profit contributed by customer  $i$  attracting new customer for corporation directly; indirect word-of-mouth marketing value  $S_1$  means a portion profit contributed through attracting new customers for corporation by the customers those who directly attracted by customer  $i$ . Then we have:

$$S_p(t_i) = S_{p0}(t_i) + S_{p1}(t_i) \quad (5)$$

$$S_f(t_i) = S_{f0}(t_i) + S_{f1}(t_i) \quad (6)$$

Where  $S_{p0}(t_i)$  and  $S_{p1}(t_i)$  mean direct and indirect word-of-mouth marketing value of customer  $i$  at the past period  $t_i$  respectively.  $S_{f0}(t_i)$  and  $S_{f1}(t_i)$  mean direct and indirect word-of-mouth marketing value of customer  $i$  at the future period  $t_i$  respectively. We can calculate  $S_0$  and  $S_1$  as follows:

$$S_0(t) = m(t) \cdot c \quad (7)$$

$$S_1(t) = \{E(X_{t_i}) - E(X_{t_{i-1}})\} \cdot p \cdot \lambda \cdot m(t) \cdot c \quad (8)$$

Where  $m(t)$  is the number of customers that directly attracted by customer  $i$  at period  $t_i$ ,  $E(X_{t_i})$  is the expect number of customers from period 0 to period  $t_i$ . And  $c$  is the cost that the corporation attracts a new customer by itself.  $\lambda$  is a parameter represents profit sharing ratio of indirect word-of-mouth marketing value ( $\lambda$  can fix on by consulting percentage take from sell profit and relational experience).  $p(t)$  is ratio that the new customers attracted by customers in the whole new customer at period  $t_i$ , namely the ratio of attracting new customers by word-of-mouth communication, generally speaking, for different commodities, the word-of-mouth communication have different effects [10]. To calculate  $S_1(t)$ , we simplified  $p(t)$  by  $p$ , which is a certain constant. Then  $S_1(t)$  can be calculate by

$$S_1(t) = \{E(X_{t_i}) - E(X_{t_{i-1}})\} \times p \cdot m(t) \cdot c \cdot \lambda \quad (9)$$

Word-of-mouth communication has the same characters as virus spread, as a result, word-of-mouth communication marketing has been called virus marketing [11]. So we use the epidemic model [12-13] to calculate  $E(X_{t_i})$ , and also discrete mathematics [14] model is used to build the word-of-mouth communication model. Now we consider a group of consumers with  $N$  people in a certain region, then  $N$  means the maximum consumers can be attracted as new customers for a corporation (attracted by either customers or corporation itself). We number the group consumer with  $a_1, a_2, \dots, a_N$ , and define set

$A = \{a_1, a_2, \dots, a_N\}$ . The word-of-mouth communication among consumer is very complex, we simplified it here and define it as a binary relation on  $A$ , i.e.  $R_A = \{ \langle a_i, a_j \rangle \mid a_i, a_j \in A, i \neq j, a_i \text{ transmits information to } a_j \}$ , we call  $a_i$  transmitter and  $a_j$  receiver in the binary relation. Then we define set  $C = \{a_i \mid a_i \in A, a_i \text{ has been the customer of corporation}\}$ . Research is start from the beginning of the production(or service) come into group consumer  $A$ , at this time, there is a people  $a_i$  among the group consumer who buy the production(or service) and become the first customer of the corporation. Then the condition that another people  $a_j$  among the group consumers is attracted by the first people  $a_i$  can be described as:

$$\langle a_i, a_j \rangle \in R_A \cap (a_i \in C) \cap (a_j \notin C);$$

Let  $X_{t_i}$  be the number of customers of the corporation in  $A$  at period  $t_i$ , then  $\{X_{t_i}, t_i \geq 1\}$  forms a discrete stochastic process. And  $E(X_{t_i})$  is the number of the corporation's customer at period  $t_i$ ,  $(N - E(X_{t_i}))$  is the number of potential customers of the corporation. Then during the  $M$  times transmissions between period  $t_i$  and period  $t_i + 1$ ,  $\frac{M}{N} \times E(X_{t_i})$  is the expected number of people who are not only the transmitter but also the customer of the corporation,  $M \cdot \frac{M}{N} \times E(X_{t_i})$  is the expected number of people who are receivers but not belong to set  $C$ . According to the hypothesis and stochastic process of transmission, after the series of transmissions,  $\frac{M}{N} \times E(X_{t_i}) \times \left(1 - \frac{E(X_{t_i})}{N}\right)$  is the expect number of new customer of corporation that attracted by the customer. Then we have:

$$\begin{aligned} & (E(X_{t_{i+1}}) - E(X_{t_i})) \times p \\ &= \frac{M}{N} \times E(X_{t_i}) \times \left(1 - \frac{E(X_{t_i})}{N}\right) \\ &= \frac{M}{N^2} \times E(X_{t_i}) \times (N - E(X_{t_i})) \end{aligned} \quad (10)$$

Let

$$k = \frac{M}{N^2 p} \quad (11)$$

Then

$$E(X_{t_{i+1}}) - E(X_{t_i}) = k \times E(X_{t_i}) \times (N - E(X_{t_i})) \quad (12)$$

So

$$\frac{E(X_{t_i+1}) - E(X_{t_i})}{(t_i + 1) - t_i} = k \times E(X_{t_i}) \times (N - E(X_{t_i})) \quad (13)$$

Regard  $E(X_{t_i})$  as a discrete value of a continuous function  $f(x)$  at  $x = t_i$ , according to Eq.(13), the differential equation of  $f(x)$  is:

$$\frac{df(x)}{dx} = k \times f(x) \times [N - f(x)] \text{ and } f(0) = 1 \quad (14)$$

Solve the equation, we can get

$$E(X_{t_i}) = \frac{N}{1 + (N - 1) e^{-t_i \times k \times N}} \quad (15)$$

#### 4. CONCLUSION

This paper analyzes factors which influence LTV and their methods of influencing at first, points out that, among all researches on calculating LTV of a customer, no one of them considered about the word-of-mouth marketing value. And then the paper suggests a new LTV model considering the past profit contribution, potential profit, customer loyalty and word-of-mouth marketing value. The model gives a more complete calculation of customer LTV and can be used for customer segmentation especially in the market which word-of-mouth marketing can make good effects.

## ABSTRACT

Continual advances in information technology (IT) have opened new business opportunities in global marketplaces. As a result, many businesses have turned to CRM to gain greater insights into their customers and apply this knowledge toward forging long-term relationships with them. This study examines the relationships of CRM practices (marketing and operational programs) with three antecedent elements (IT investments, absorptive capacity, strategic alignment), CRM effectiveness and firm (business) performance. The results of a survey suggest the following: absorptive capacity and strategic alignment have positive effects on CRM practices, CRM practices affect CRM effectiveness, CRM effectiveness affects firm performance, and CRM effectiveness mediates the effect of CRM practices (marketing programs) on firm performance. Hence, the CRM practices a business adopts will have an impact on its performance.

**Keywords:** customer relationship management, information technology, absorptive capacity, strategic alignment, CRM effectiveness

## 1. INTRODUCTION

Continual advances in information technology (IT) have opened the world of electronic commerce (e-Commerce) for businesses to pursue global marketplaces. Predictions for 2005 suggest that worldwide e-commerce will exceed \$5 trillion USD, which will be fueled by over a billion Internet users [13], [17], [25]. In contrast, International Data Corporation estimated the e-commerce market at \$1 trillion for 2003.

Yet, as more businesses enter the Internet-enabled electronic marketplace, competition becomes keener. In seeking means that provide greater competitive advantages, many have turned customer relationship management (CRM), commonly described as an information system to assist the customer retention process or a methodology that extensively employs IT, particularly database and Internet technologies, and enhance relationship marketing (RM) effectiveness and operational practices.

CRM helps a business identify its most valuable customers, and develop, integrate and focus its competencies on forging valuable long-term relationships that deliver superior value to them [20]. It behooves the business to identify and understand these customers to ensure future performance and profitability. However, achieving success also requires investments in technological resources and a clear vision of the business' direction and purpose. Consequently, an understanding of the relationship among the factors that affect and influence CRM practices and performance underlie the achievement of CRM effectiveness and eventually the business'

performance.

This study examines the relationships surrounding CRM practices and its eventual effect on a business' performance. It proposes that three vital antecedent elements, IT investments, organizational absorptive capacity and strategic alignment, shape the CRM practices a business adopts, such as those for its marketing and operational programs. Furthermore, these CRM practices will impact its CRM effectiveness and eventually its performance. Because the three elements reflect the degree to which the business has enriched itself, they represent the building blocks that extend the capabilities of CRM. However, in this successive relationship, CRM effectiveness will mediate the effects of its practices on its business performance. Investments to the practices will affect performance but only if they impact CRM effectiveness. Furthermore, the competitive nature of the industry will moderate the effects of CRM practices on CRM effectiveness. Because businesses respond to market pressures according to the competitive intensity of its industry, practices will vary. Given the interactions of these factors, *how do investments in CRM impact the business' performance?*

## 2. BACKGROUND

CRM provides a business with an enterprise approach to understanding and influencing customer behavior through meaningful communication. It involves targeting the right customer with the right product or service through the right channel at the right time (Swift, 2001), attracting (acquiring), developing and maintaining successful customer relationships over time

[4], [7], and building customer loyalty [15] through efficient and effective two-way dialogues [19]. As a result, CRM improves a business's ability to acquire and retain customers and build their loyalty, a competitive asset [8].

The insights a business gains through CRM lead to customized products and services that more precisely match its customers' needs and impede competitors from duplicating, imitating or substituting them [18], [24]. With these refined and appealing offerings, a business can expect not only greater satisfaction and continued patronage from its customers, but other benefits in the form of reduced costs and sustained profitability.

Through advanced computing power and high-speed communication networks over the Internet, CRM allows businesses to continually learn about and monitor their customers' needs and expectations, and innovatively respond to them [19]. As a result, businesses can adopt more customer-centric marketing strategies (as opposed to mass-marketing strategies). IT also allows an organization to quickly collect, store, manipulate and disseminate information throughout its operations and with other businesses, such as its supply chain partners, to increase its organizational knowledge and improve its operational efficiencies. IT-based knowledge discovery techniques (i.e., marketing intelligence), such as data mining, online analytical processing (OLAP) and intelligent agents provide the means for building organizational knowledge and further leveraging it for a competitive advantage or profitable gain. Operational benefits involve activities and programs targeting efficiency gains and profitability.

CRM embodies many of the concepts of relationship marketing (RM), a marketing paradigm that focuses on developing close personal relationships, interactions and social exchange between a business and its customers and business partners over time to enhance the its (business') competitive response to continually changing markets [26]. CRM expands upon this concept through its emphasis on information management [18]. Thus, CRM helps focus the business on achieving personal long-term relationships with its customers through information gathered to form a deep understanding of their characteristics, behaviors, needs and expectations, and draw closer to achieving a one-to-one relationship. As a management tool, it directs enterprise resources towards the fulfillment of the organization's goals and objectives.

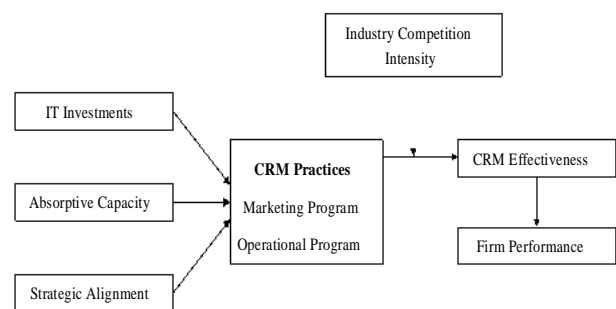

A business's success with CRM also lies with its execution or practices. CRM practices refer to the actions a business takes to retain its current and attract potential customers through personal touches in fulfilling and satisfying their individual needs. Expanding upon the foundational studies of Applegate et al. [3] and Karimi et al. [12], CRM practices can be

divided into two categories: CRM marketing programs and CRM operational programs.

A business's success with CRM will contribute to its (business) performance. However, this depends on the presence of factors and a sequence of relationships that represent different aspects of CRM. This study examines the interactions tied to achieving success with CRM.

### 3. RESEARCH MODEL AND HYPOTHESES

Figure 1 illustrates the research model of this study. The model proposes that a business's investments in IT and absorptive capacity, and its commitment to strategic alignment (of IT and the business' strategy) will positively affect its CRM practices (marketing and operational programs), and consequently its CRM effectiveness and (firm) performance. The model also proposes that CRM effectiveness will mediate the effects of CRM practices on firm performance, and industry competition intensity will moderate the effects of CRM practices on CRM effectiveness.

**Figure 1 . Research model**

Because of CRM's reliance on IT, IT investments determine the extent of CRM's capabilities to support the business's endeavors. The greater the investments the more reasonable it is to expect greater achievements. Thus, IT investments play a major role in shaping CRM practices.

*H1: IT investments have a positive relationship with CRM practices*

*H1a: IT investments have a positive relationship with CRM marketing programs*

*H1b: IT investments have a positive relationship with CRM operational programs*

Organizational absorptive capacity forms the basis for organizational knowledge and the business's ability to innovate. It results from the cumulative learning activities of the organization's individuals and the transfer of knowledge within the organization through a common language [6]. Organizations that have amassed knowledge of their market requirements and

customers' needs are more inclined toward practicing marketing intelligence and information sharing to produce knowledge, and leveraging information and knowledge to satisfy their customers with the goal of gaining their loyalty.

*H2: Absorptive capacity has a positive relationship with CRM practices*

*H2a: Absorptive capacity has a positive relationship with CRM marketing programs*

*H2b: Absorptive capacity has a positive relationship with CRM operational programs*

Because IT enables CRM and extends its capabilities, the strategic alignment between a business' IT and business strategies will impact CRM practices. The alignment reinforces the success of CRM practices. The degree to which strategies align (i.e., strategic alignment) will impact CRM practices, with greater alignment resulting in better practices.

*H3: Strategic alignment has a positive relationship with CRM practices*

*H3a: Strategic alignment has a positive relationship with CRM marketing programs*

*H3b: Strategic alignment has a positive relationship with CRM operational programs*

CRM effectiveness reflects the success of CRM practices. In particular, it examines the outcomes of the business' practices in achieving customer benefits, including social, psychological, economic and customization [9], and business benefits, such as those related to cost reductions, profitability and efficiencies. Thus, greater achievements in CRM practices will be associated with greater heights of CRM effectiveness.

*H4: CRM practices have a positive relationship with CRM effectiveness*

*H4a: CRM marketing programs have a positive relationship with CRM effectiveness*

*H4b: CRM operational programs have a positive relationship with CRM effectiveness*

Prior studies have found a positive link between customer satisfaction and business (firm) performance [1], [2]. Customer loyalty can increase firm performance through the reduction of acquisition and operating costs, and increases in (customer) price tolerance and referrals [11], [16], [22]. Thus, greater levels of CRM effectiveness should have a positive impact on firm performance.

*H5: CRM effectiveness has a positive relationship with firm performance*

Reichheld and Sasser [22] cite a high correlation between customer retention and profitability, such that a five percent increase in customer retention yields improvements in long-term profitability (as stated in terms of net present value) between 20 and 85 percent. Thus, improved CRM practices should have a positive effect on firm performance.

*H6: CRM practices have a positive relationship with firm performance*

*H6a: CRM marketing programs have a positive relationship with firm performance*

*H6b: CRM operational programs have a positive relationship with firm performance*

Businesses will eventually derive benefits from their CRM practices but through CRM effectiveness. Although CRM practices reflect a business' proficiency in leveraging its IT, absorptive capacity and strategic alignment between IT and business strategies, a business will directly benefit from the effectiveness of CRM (i.e., performance attributed to CRM). Given this relationship, CRM effectiveness will mediate the effects of CRM practices on firm performance.

*H7: CRM effectiveness mediates the relationship between CRM practices and firm performance*

*H7a: CRM effectiveness mediates the relationship between CRM marketing programs and firm performance*

*H7b: CRM effectiveness mediates the relationship between CRM operational programs and firm performance*

The role of competition intensity influences a business' responsiveness to customer needs and expectations through product and service offerings [21]. Prior studies have shown the importance of competitive threats to innovation diffusion [5], [14]. Hence, industry competition intensity may influence CRM practices for its effect on CRM effectiveness.

*H8: Industry competition intensity moderates the relationship between CRM practices and CRM effectiveness*

The operational definitions to measure the variables (constructs) were taken from prior studies to test the hypotheses.

#### 4. METHODOLOGY AND ANALYSIS

A survey was conducted on a stratified sample composed of 598 randomly selected companies listed in

the Taiwan Stock Exchange (TSE) (438) and on the over-the-counter (OTC) markets (160). Items were adopted from prior studies and stated on five-point Likert-type scales (1 = strongly disagree, 5 = strong agree). The survey instrument was pre-tested on six experts and managers with extensive CRM practice experiences to elicit their comments and opinions. Subsequent adjustments to improve the questionnaire's clarity were made.

The questionnaires were mailed with a cover letter explaining the purpose of the survey and instructions on its completion, and a return envelope. A total of 161 responses were received for a response rate of 26.9 percent. However, nine questionnaires were returned incomplete and discarded. This reduced the sample size to 153 responses (25.6 percent response rate). A test for sampling bias showed no significant differences among the composition of the sample, the surveyed groups and industry (TSE and OTC). Also, no significant differences were found in a test for non-response bias that compared early and late responses.

A confirmatory factor analysis (CFA) was conducted to assess the discriminant and convergent validity of the items. The values obtained for the measures assess their (measures') validity which is inferred if a measure's factor loadings meet or exceed a criterion value of .40. The results indicate an acceptable level of convergent and discriminant validity.

The maximum likelihood estimation method was used to estimate the structural equation model (SEM) in LISREL 8.3. Figure 2 shows the path loading and coefficient alphas of the constructs. Table 1 summarizes the LISREL estimates and Cronbach alphas of the latent variables.

The analysis of the results generally supports the research model, although not all hypotheses are supported (Table 1). Of the three factors leading to CRM practices, two appear to have positive relationships. The effects of IT investments on CRM marketing and operational programs were not significant (H1 not supported). In contrast, the effects of absorptive capacity and strategic alignment on both CRM practices variables were found significant (H2 and H3 supported). This suggests that organizational factors consistently influence CRM practices, more often than IT investments. Although, IT investments are important to businesses, they may not be a primary consideration to an organization's intended use of CRM. Also, it may be assumed from a practical view point that IT is an integral part of CRM, such that CRM does not exist without IT. This lends further support to CRM as an RM solution and not one of IT.

The data support the positive relationships between CRM practices and CRM effectiveness (H4 supported),

and CRM effectiveness and firm performance (H5 supported). Both marketing and operational programs play vital roles in achieving CRM effectiveness. Marketing programs focus resources on customer sales, service and support, and essential interface elements for ensuring continued patronage. They strive to gain the trust and confidence of the customer. With operational programs, activities center on the logistics of product and service delivery, ensuring their timely and satisfactory delivery. Both programs are important to the longevity of business' relationship with its customers, particularly to maintain customer satisfaction. The support of H5 suggests that maintaining customer satisfaction and loyal (CRM effectiveness) are important aspects of a business that are tendered through CRM. Because CRM practices enhance CRM effectiveness and CRM effectiveness in turn increases a business' performance, improving the practices will have an eventual impact on firm performance.

In the relationship between CRM practices and firm performance, only CRM operational programs have a positive relationship (H6b support); CRM marketing programs are not significant (H6a not supported). Unlike operational programs, the outcomes of marketing programs tend to be intangible and measured in non-monetary terms (i.e., customer satisfaction, loyalty, etc.). Because operational programs objectives and firm performance are gauged monetarily (i.e., costs, profits), both are compatible for measurement under the same terms and sharing a consequential relationship (i.e., one leading to the other).

The results of H4, H5 and H6 (Table 1), and the significant correlations between CRM marketing program and firm performance, and CRM operational program and firm performance suggest that CRM effectiveness mediates the relationship between marketing programs and firm performance (H7a supported) and only partially mediates the relationship between operational programs and firm performance (H7b partially supported). A mediating effect occurs when variations of the independent variables account for variations in the mediator, variations in the mediator account for variations in the dependent variable, and when controlled the independent variables have no effect on the dependent variable. The absence of a direct impact of marketing programs on firm performance (H6a) and the presence of relationships between marketing programs and CRM effectiveness and CRM effectiveness and firm performance indicates the effects have been mediated by CRM effectiveness. However, the presence of positive relationships revealed by H4b, H5 and H6b suggests CRM effectiveness only partial mediates the relationship between operational programs and firm performance.

Although prior studies suggest that competition intensity influences business practices, this study's results do not support a moderating effect of industry

competition intensity on the relationship between CRM practices and CRM effectiveness (H8 not supported). A moderator enhances (or reduces) the effect of the independent variables on the dependent variable. A multiple regression model was developed to test for the moderating effect. Because the interaction of CRM practices and industry competitive intensity is not significant, a moderating effect does not exist (Table 4). Upon further inspection, the data reveal a high mean (4.09) for the measure of competition intensity. This infers that competition intensity does not vary over industries and it becomes indistinguishable. Thus, factors other than competition intensity influence CRM practices.

The maximum likelihood estimation method was used to measure the overall fit of the model (in LISREL 8.3). Hoelter [10] suggests that the data are supportive of the model when the Critical N (CN) exceeds 200. The sample's CN of 519.16 indicates the data appropriately fit the model. The goodness of fitness indicators summarized in Table 5 also indicates a good fit.

**Table 1.** Summary of test hypotheses

Hypothesis	LISREL Estimates	t-value	Cronbach Alpha	Result
H1a	0.02	0.18	0.957 (IT investments)	Not supported
H1b	0.18	1.78		Not supported
H2a	0.37	4.37	0.922 (Absorptive capacity)	Supported
H2b	0.27	3.58		Supported
H3a	0.41	3.49	0.941 (Strategic alignment)	Supported
H3b	0.65	5.44		Supported
H4a	0.51	7.11	0.787 (Marketing programs)	Supported
H4b	0.46	7.00	0.854 (Operational programs)	Supported

H7a	-	-		Supported
H7b	-			Partially Supported <sup>1</sup>
H8	-	0.272		Not Supported

## 5. CONCLUSIONS

As more businesses enter the global electronic marketplace and engage in e-Commerce, competition among them intensifies. To better serve their customers and gain their loyal, many have turned to CRM. Understanding the relationships among the elements and components that make up CRM will lead to more effective use of CRM and a greater contribution to profitability. This study has shown that an

organization's investments in absorptive capacity and commitment to aligning its IT and business strategies play largely in forming CRM practices (marketing and operational programs). Significant boosts to CRM practices will lead to greater CRM effectiveness, which in turn contributes to profitability. Thus, businesses entering e-Commerce and investing in CRM should understand the organizational commitments and activities surrounding a CRM implementation. Although IT enables many aspects of e-Commerce and integrates activities across organizational boundaries, its role in CRM other than an enabler and integrator may not be assumed as an essential part of CRM. Thus, achieving CRM effectiveness lies in how the business leverages and exploits its knowledge.

## ABSTRACT

“The Intelligent Model for Stock Investment with Buffett Strategy, Classifier System, Neural Network and Linear Programming” was studied for developing an intelligent model which can learn more knowledge regarding to stock investment with artificial intelligence technology. Classifier system, neural network, fundamental financial investment factors and linear programming are the fundamental components for the research. Knowledge transformation and genetic evolution capability was discussed in the article, too. Furthermore, the investment strategy developed by Warren E. Buffett[17], the great financial investment master, was the major knowledge which was practiced in the article.

For realizing more detail about learning system, a lot of topics regarding to artificial intelligence were discussed in advanced, including “A Market-Based Rule Learning System” [1], “Dynamic Trading Strategy Learning Model using Learning Classifier System” [2], “Nonlinear Index Prediction” [3], “Financial Decision Support with Hybrid Genetic and Neural Based Modeling Tool” [4] and “Fuzzy Interval methods in Investment risk Appraisal” [5].

According to the study mentioned above, the ideas to give intelligent model, especially with genetic algorithm, bring the direction for the advanced financial investment strategy and operation. Therefore, it was why a novel intelligent model with Buffett strategy, classifier system, neural network and linear programming proposed in the article.

**Keywords:** Classifier System, Security Investment, Buffet, Neural Network, Linear Programming

## 1. INTRODUCTION

In the world of financial investment, everybody is looking forward to raising the investment visibility and get profit through transparent financial investment model. However, people are confused by too many kinds of merchandize, and suffered by the high complexity with so many connections among all investors from different security and trading market. It is possible but really difficult to award the profit in the mazy trading environment.

Trading in stock market is the most popular financial investment. The shaky price in stock market brought the possible super profit. The entry barrier to involve trading in stock market is low, too. The market price and related financial information is easy to take. It is the reason why the population of involving stock market is very high in anywhere.

For providing more intelligent technology in financial investment prediction, only the research in classifier system, neural network, linear programming, and fundamental intelligent financial investment operation, but also the investment criteria developed by Warren E. Buffett [6][17][18] was adopted for the improving the intelligence of financial investment operation.

This was why the research including linear

programming, neural network, classifier system, fundamental financial investment factors and Buffett investment criteria were taken in the article. The intelligent model can be constructed by integrating these methodologies. Through the developed intelligent model and related information, the most effective rules can be retrieved for supporting financial investment decision making. The fundamental factors are wisdom-base mining operations in the intelligent model. Therefore, Buffett strategy was taken for representing the knowledge of mid-term / long-term financial investment. Furthermore, in the article the knowledge will not be limited on the idea from Buffett Strategy, but also including any financial knowledge if they will be useful for predicting the stock price in the changeable world.

## 2. RELATED WORK

### 2.1 Linear Programming

The Linear Programming (LP) [7] is the model which represents the objective system functions and related behavior. The basic definition of LP can be described as below:

**Object function :** minimize  $cx \dots(1)$   
**Subject to**  $Ax = b \dots\dots\dots(2)$   
 $x \geq 0 \dots\dots\dots(3)$

Where  $\mathbf{x}$  is the multi-dimensional variable vector associated with coefficient matrix  $\mathbf{A}$ ,  $\mathbf{c}$ ,  $\mathbf{b}$  are coefficient vectors, the formula (2) and (3) are constraint conditions. The formula (1) is the objective function in the linear programming.

Normally, for a specific objective function, there are quite a lot dimensions and variables. To simplify the complexity of given problem, the linear programming model, normally, was constructed with limited factors. So, it is necessary to construct a dynamic intelligent model for intensifying financial investment prediction.

## 2.2 Neural Network

As what we knew, all the messages what human can feel are dispatched by network system with neuron and delivered to brain for further decision making. Neural network [8] which was defined in information technology simulates the operation, transmits the messages from sender through given activation function in each "cell" to receiver.

As the definition of neural network mentioned above, any cell in neural network normally gives different activation function within it. A sample of a cell in neural network can be depicted as the figure as below:

Figure 2 : A Sample of A Cell in Neural Network

where, for each input  $W_i = 0$  or  $1$

$$F(W_i) = \begin{cases} 2/3, & \text{if } 1/2 W_1 + 1/3 W_2 + W_3 + 2/3 W_4 + 3/5 W_5 \geq 1.5 \\ 0, & \text{if } 1/2 W_1 + 1/3 W_2 + W_3 + 2/3 W_4 + 3/5 W_5 < 1.5 \end{cases} \quad (4)$$

The value  $R$  is the return of activation function in the given cell. It got the 5 input sensors and forward to next stage (may be the other cell). The value 1.5 for function  $F(W_i)$  is the "Threshold Value" for the cell's activation function. Each input which is associated with a "weight" can be defined as a factor for decision making in  $R$ . Each "weight" for corresponded "input" is normally independent to the other "weight" for the cell in neural network.

## 2.3 Classifier System

Classifier System [9] is the major research model for evolutionary computation in artificial intelligence. It is an intelligent learning mechanism with rules of expertise, messaging between rules and parallel process. Within the organization of classifier system, for intensifying the message delivery between rules, the Bucket Brigade Algorithm [10] was taken for solving Credit Assignment [11] in system. In addition, for self-creating new rules, classifier system was improved as a new expert system which can be the rules set with genetic algorithm. Each rule adopted in the system is treated as a *classifier*. Therefore, the operational mechanism for the whole classifier system is constructed on the evolutionary concept with information transmission and credit exchange among all classifiers. The system structure of whole classifier system can be depicted as figure 3 :

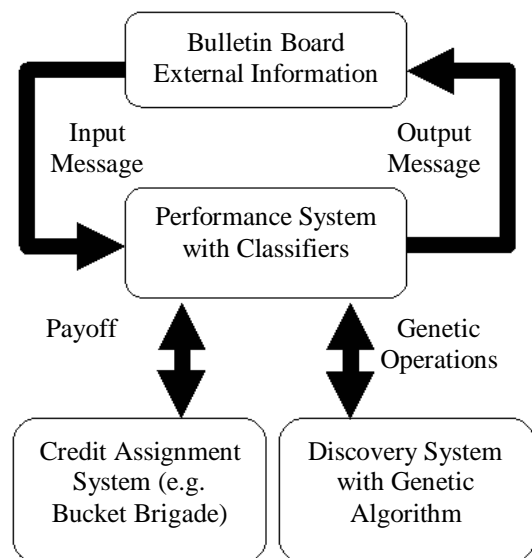

Figure 3 : The System Structure of Classifier System

In the classifier system, the Performance System Module is located on kernel [12]. It is also the system module which connects to message outside. It is looked like an expert system but not limited on specific knowledge domain. Although it is rule-based system module, however, it still needs the additional system which can help to process the outside messages via information transmission, high degreed standardized action and parallel processing capabilities, and can tell the advantages from each classifier in the system.

The 2<sup>nd</sup> major system in classifier system is Credit Assignment System which can tell the advantages from different classifier, and evolve them via tuning credit. Normally the Bucket Brigade Algorithm was taken for processing the functionality. According to the definition of credit assignment, the Bucket Brigade Algorithm is designed for telling the right rules under a rule-based classifier system. Also by the Bucket Brigade Algorithm, better rules will be rewarded with more credits and worse rules will be punished. Each classifier in the credit assignment system indicates its own credit level.

Through the Bucket Brigade Algorithm the credit level for each classifier will be tuned by corresponded contribution in outside message handling. Also, the classifier can bid and obtain the right to handle outside message if it got highest credit level among all competitive classifiers.

The 3<sup>rd</sup> major system in classifier system is Rule Discovery System[13]. For the evolution after the competition among all classifiers, the portion of useful classifier is probably the minority in the whole classifier rule base. With the minority portion of classifier, it cannot be the answer to find the best set of classifiers so that the new classifiers (rules) should be generated via certain experience and evolutionary criteria. That is, the new classifiers are expected to generate either from existed excellent classifiers, or changing existed classifiers.

## 2.4 The Factors of Security Financial Investment

Security financial investment must be defined in term of market behavior. The market behavior, from fundamental viewpoint, is the supply – demand operations in term of economic activities [14]. The pricing is determined by the supply – demand operations, too.

The impact to price from supply – demand operations cannot be briefly explained with marketing trading. For buyers in stock market, the investment can be defined as two portions: stocks on hand and stakes for buying. Of course, for sellers in stock market, the investment can be defined with opposite way: stakes on hand and stocks for selling. Therefore, the timing for tuning stocks and stakes is taken as the strategy of investment.

In addition, for considering the balance of supply – demand relation made by quantity and price in stock market, the factors of analysis including technique, fundamentality, industry development, macro economics, information and stake, are the keys [15]. The motivation for investment including venture, risk prevention and profit locking, drives the balance of trading market in terms of operation model and momentum [16]. These factors above were discussed in the article.

## 2.5 Buffett's Criteria in Financial Investment

The philosophy of Buffett's financial investment is: "Search and invest the healthy enterprise entity if its stock price is much underestimated. Keep the stocks as long-term then the profit generated via compound interest will return." Therefore, the enterprise that Buffett preferred to invest got the characteristics listed as below [17]:

1. The enterprise gets the position of monopolization. The population of products is good. Business is

reliable and can be developed as well in the future.

2. The enterprise got reliable financial situation. The management performance is excellent. The capital investment is little and cash flow is sufficient.
3. If the enterprise is found by the conditions above, then evaluate the related internal value thereafter. If the current stock price of the enterprise is much less than the value after evaluation (normally the current stock price is 30% less than internal value), then the enterprise is deserved to invest.

When Buffett found the enterprise which met the conditions mentioned above, then he usually ignored the oscillation of stock price, funded quite a lot stakes and bought significant portion of stocks, as the way to purchase the enterprise. Buffett kept these stocks with long-term way. The timing he sold the stock was determined with the following conditions:

1. The current stock price is more than the internal value of the enterprise after evaluation.
2. The growth of aimed enterprise becomes slow.
3. More stakes are needed for better target enterprise.

## 3. THE OBJECTIVE FUNCTION OF THE INTELLIGENT MODEL

The operation of this intelligent model with classifier-based neural network and Buffett strategy can be explained by Figure 4:

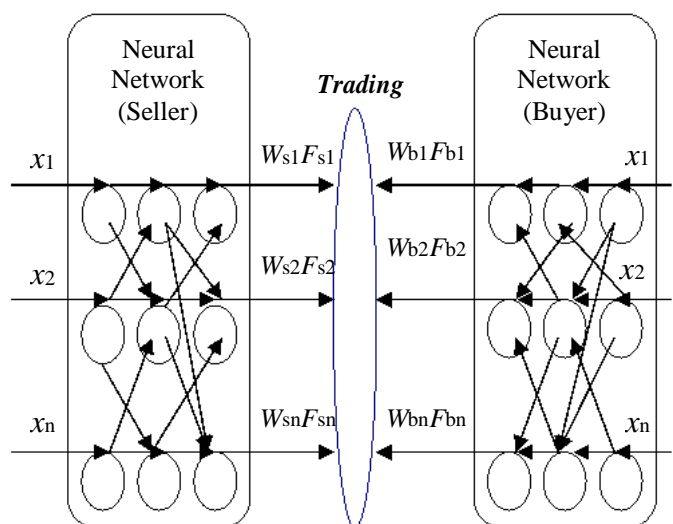

Figure 4 : The Intelligent Model with Classifier-based Neural Network and Buffett Strategy

In Figure 4,  $W_{si}F_{si}$  and  $W_{bi}F_{bi}$  stand for the investment decision making information for the sellers and the buyers. Take the sellers as an example,  $F_{si}$  represents the  $i^{\text{th}}$  classifier of the seller party in the neural network,

and  $W_{si}$  symbolizes the weighted function of the classifier  $F_{si}$ . Formula (7) and (8) illustrate the definitions of these two function variables for the buyer party in the investment model, and the objective function is illustrated in formula (5) and (6).

**Object function :**  $\text{minimize } |P_r(t) - P(t)| \dots \dots (5)$

**Subject to:**

$$P(t) = P(t-1) + \sum_{i=1}^M F_{bi}(t-1) \cdot W_{bi}(t-1) \quad (6)$$

where

$$F_{bi}(k) = PE_{stock_i} \times EPS_{stock_i} \times \sum_{k=t-10}^{t-1} PBT \times \sum_{k=t-12}^{t-1} GRP \quad (7)$$

$W_{bi}(t-1)$  = the proportional weight in all classifiers of stock  $i$  in time  $t-1$  .....(8)

$P_r(t)$  denotes the real stock price in time  $t$ .  $P(t)$  is the expected price after investment.  $P(t-1)$  represents the present stock price before investment. The neural function in classifier system is shown in formula (6) where  $M$  is the number of stocks that  $F_{bi}(t)$  and  $W_{bi}(t)$  are adopted. We can observe the behavior of  $F_{bi}(t)$  by formula (7).  $W_{bi}(t)$  represents the weighted function in time  $t$ , as shown in formula (8). The object of this model, as stated in the objective function shown in formula (5), is to minimize the difference between  $P(t)$ , the expected stock price, and  $P_r(t)$ , the actual stock price in time  $t$ .

Obviously these functions  $F_{bi}(t)$ ,  $F_{si}(t)$ ,  $W_{bi}(t)$ , and  $W_{si}(t)$  which determine the value of  $P(t)$ , is executed in the neural network. Say for the buyer,  $W_{b1}(t)$  is the weighted function of  $F_{b1}(t)$ ,  $W_{b2}(t)$  is the weighted function of  $F_{b2}(t)$ ,  $W_{b3}(t)$  is the weighted function of  $F_{b3}(t)$ ... and so on.  $F_{b1}(t)$ ,  $F_{b2}(t)$ , and  $F_{b3}(t)$  themselves are analyzable functions, therefore there exists respective parameters for each  $F_{bi}(t)$ . This kind of nested neural network structure befits the linear programming model well.

Defining  $F_{bi}(t)$  and  $W_{bi}(t)$  is the key issue to construct the most effective linear programming model within neural network framework. In this article, we use the "Divide and Conquer" to discover the best factor and choose the weights. The factors in the neural network framework, resulting in the linear programming model, build up a decision support system for the portfolio investment.

However, with the characteristics of dynamic linear programming, the analysis of neural network can be tuned. On the other hand, the static linear programming actually is far away from the real world. The stock investment cannot rely on such kind of model only because it will be distortive when the factors and stock environment start to change.

Certainly, the functions including  $F_{bi}(t)$ ,  $F_{si}(t)$ ,  $W_{bi}(t)$  and  $W_{si}(t)$  can be the other dynamic sub-objective functions. The precision of the related linear programming is determined by design scope, cost and the degree of detail. In the article, the way to improve the precision of objective function will be built on the realization on definition of dynamic parameters.

#### 4. THE PRACTICE OF INTELLIGENT MODEL OPERATION

There were 6 samples taken for the coming experiment. However, it did not indicate the all criteria of Buffett knowledge. Also, the rules depicted from the given 6 samples do not show up the know how of the whole research of security investment. The intelligent model for security investment with classifier system, neural network and linear programming is designed for inputting more rules or knowledge, such as Buffett strategy and investment criteria, can be input and transformed as the classifiers and be evolved in the intelligent model.

According to related reference regarding to the research of Buffett investment strategies [17][18], the rule of 6 assumed sample classifiers and corresponded format can be defined as below:

1. Classifier\_001 : To retrieve stock if current price got 30% difference less than internal value of enterprise.

Condition of Classifier	Action	State
#   0   0   0	0   1	0   1   0   1

2. Classifier\_002 : To retrieve stock if current price got 40% difference less than internal value of enterprise.

Condition of Classifier	Action	State
#   0   0   1	0   1	0   1   0   1

3. Classifier\_003 : To retrieve stock if current price got 50% difference less than internal value of enterprise.

Condition of Classifier	Action	State
#   0   1   0	0   1	0   1   0   1

4. Classifier\_004 : To retrieve stock if current price got 60% difference less than internal value of enterprise.

Condition of Classifier	Action	State
#   0   1   1	0   1	0   1   0   1

5. Classifier\_005 : To retrieve stock if current price got 70% difference less than internal value of enterprise.

Condition of Classifier				Action		State			
#	1	0	0	0	1	0	1	0	1

6. Classifier\_006 : To retrieve stock if current price got 80% difference less than internal value of enterprise.

Condition of Classifier			Action			State			
#	1	0	1	0	1	0	1	0	1

For the 6 sample classifiers, the input message, output message, classifier function for telling the difference between current stock price and internal value of enterprise, and weighted function of bidding value can be depicted as below:

¢ Input Message : including stock ID, PE, EPS, the profit rate before tax for past 10 quarters, revenue growth rate for past 12 months, the current price of the stock.

¢ Output Message : same as input message, including stock ID, PE, EPS, the profit rate before tax for past 10 quarters, revenue growth rate for past 12 months, the current price of the stock.

¢ Classifier Function to Tell the Difference : ((PE) X (EPS) X (the profit rate before tax for past 10 quarters) X (revenue growth rate for past 12 months)) X (Condition)% >= (current price of stock).

¢ The weighted function of bidding value : 10% of the proportional weight in all classifiers.

The factors to evaluate stock value can be depicted with PBT (The Profit before tax), S.P (Current Stock Price) and margin is described as Table 1 as below :

Table 1 : The Factors To Evaluate of Stock Value

EPS	PE	12M GRR	PBT	Value	<Date> S.P	Margin
2.40	20.00	3.04%	-0.24%	49.34	20.5	140.6%

According to the message format defined above, the stock value which is evaluated by classifier can be depicted as formula as below:

$$\text{Stock Value} = \text{EPS} \times \text{PE (in Industry)} \times (12\text{M GRR}) \times \text{PBT} \dots\dots\dots(9)$$

In the Table 1, 12M GRR (Growth Rate in term of Revenue) indicates the growth rate in term of monthly revenue in past 12 months. PBT indicates the profit rate before tax in past 10 quarters. Certainly, the regulation in the classifier is not necessary calculated by mean value but by the other buffett investment philosophy. For easily describing how to transform buffett

investment strategy as a classifier, the assumed factors and regulation mentioned above are taken for designed as “Buffett Classifiers” for practice.

Furthermore, why the both “12M GRR” and “PBT” are taken for designing a type of “Buffett Classifiers”?

1. According to the research of Buffett investment strategy, for preventing the error caused from stock price oscillation, the time period which is taken for information collection must be longer. The time period with 12 months or 10 quarters is a proper and reasonable default value to converge the performance of business operation and stock price.
2. The internal value of stock price for given enterprise, EPS and PE are the fundamental factors. However, the value of enterprise should be assessed according to operation performance and capability to make profit. Therefore, the factors “12M GRR” and “PBT” are taken as the parameter to evaluate the stock price. Note that the Buffett’s attitude of stock investment was similar to “purchase the enterprise” rather than the gamble way.

So, the minimization of difference between  $\mathbf{Pr(t)}$  and  $\mathbf{P(t)}$  is objective function in the article. This is the design target for the proposed intelligent model. The mathematic characteristics in the intelligent model are also the research objectives in the article.

Note that the criteria within the assumed classifiers are not indicated high precision in stock price prediction. Probably some stronger classifiers have shown right assessment via giving internal value for the related enterprise. It must have some other weaker classifiers that never give right prediction. The point in the article is “the environment” for rules evolution from the structure and mechanism in the proposed intelligent model. The stronger classifiers that provide right answer in stock price prediction can be evolved through more investment strategies and learning via the genetic evolutionary process.

## 5. CONCLUSION

Through the research and practice in the article, the conclusion and additional issues were listed as below :

1. The intelligent model for stock investment with Buffett strategy, classifier system, neural network and linear programming got a lot of advantages in system learning and intelligence evolution. Any kind of valuable knowledge, even wisdom, such as Buffett strategy in stock investment, can be transformed and deliver into the intelligent model.
2. Through the intelligent model for stock investment, especially follow the Buffett criteria, the performance to make profit will not be carried in

very short time period. The basic learning cycle is still required.

3. The intelligent model is constructed with classifier system, neural network, fundamental financial factors and Buffett investment strategy. Obviously it integrated the research fields in artificial intelligence and financial investment. Through the study, except the useful rules can be adopted and evolved in the intelligent model, the rules with high performance of financial investment can be retrieved from the system operation.
4. All the samples and assumed classifiers are the basic objects for practice in the intelligent model. With longer practice, around more than half or 1 year, the precision of the intelligent model and stronger classifiers would be found.
5. The oscillation rate in linear credit function can be the advanced issue for research in the intelligent model. Also, the risk problem of the credit distribution among all classifier is deserved to discuss. The information in tendency or habitual domain for each classifier can be reveal from the credit assignment and genetic evolution. It would get the potential risk if no superior advisable intelligent model manages the operational intelligent model.
6. The variance beyond the system prediction should be considered. Therefore, the knowledge for high degree of stock price oscillation should be taken in linear programming.

## ABSTRACT

In the recent years, customer relationship management (CRM) has being depicted by the software vendors as a cure-alls for the enterprises which wish to acquire, maintain efficiently customer share and at last to gain more profit in globalized market with fierce competition. However, the currently popular CRM marketing practice often produces disappointing outcomes. The more popular this marketing practice gets, the more people who realize that the current CRM practice hardly manages customer relationship. Through analyzing the costs-benefits, ROI and TCO of CRM implementation, this article tries to find out a correct way to accomplish successfully CRM implementation, discuss the success factor and failure barrier of CRM projects for successful complementation of CRM.

**Key words:** Customer Relationship Management (CRM), CRM implementation, Cost-Benefit, Return on Investment (ROI), Total Cost of Ownership (TCO)

## 1. INTRODUCTION

The fundamental goal of all Return on Investment (ROI) studies is to describe how existing customers derive value from the use of a particular software product, and to extrapolate a generalizable model from those experiences that can predict the degree to which a new user will derive a measurable ROI.

Several 2003 reports claimed the ROI from CRM implementations was dismal, with 8 out of 10 projects failing to deliver on ROI promises, and 50-70 percent typical project failure rates. Some of this year's reports are more optimistic, with about 52 percent of companies responding that their CRM initiatives generated an ROI between 51 percent and 500 percent, and 30 percent of respondents saying the return was greater than 501 percent.

Many newcomer companies must decide if they should begin with a CRM initiative. Above mentioned results should have a great influence on their decision. No matter how different the results are, the companies must know as exactly as possible if the CRM project is in the long time run lucrative for them.

Before CRM project companies should be able to demonstrate ROI on their CRM investments, and they need to implement serious yardstick work when seeking to evaluate CRM-software investments and to give a clear evaluation that quantifies the expected costs, tangible financial benefits, intangible strategic benefits and risks.

In the following, we are going to discuss thoroughly costs, benefits and ROI problems.

## 2. COST-BENEFIT ANALYSIS OF CRM IMPLEMENTATION

In order to establish a business case for pre-project planning, and post-project success measurement, we must assess implementation costs, benefits, and risk.

### i. Implementation Costs

Basically, implementation costs are should include CRM software licensing and maintenance or support contracts; EDI, database, operating system and other software licensing and maintenance or support contracts; hardware purchases and maintenance or support contracts including servers, storage and network upgrades (as required); software integration and customization, including design, development, test and ongoing maintenance; implementation labor; ongoing administration and support labor; planning and requirements meetings; user training and learning time; and process change management.

### ii. Tangible and Intangible Benefits

As table 1 described, generally speaking, benefits typically include increases in staff productivity, cost avoidance, increased revenue and margin, and reduced inventory through the elimination of errors. Benefits could be divided into tangible and intangible benefits.

<sup>\*</sup> Sponsored by Special Scientific Research Fund for Doctoral Education Base of Higher School (20030614011), National Science Fund of Excellent Youth(79725002)

**Table 1 CRM benefits and improvements**

Key Benefit Area	Key Improvement
Reduce cost of sales	Enable self-service sales channels, changing the mix of direct sales, tele-sales, channel or agent sales, and self-service the most effective or least costly channel in order to reduce costs and improve satisfaction
Reduce sales administrative overhead	Reduce the time spent on sales administrative overhead tasks such as commission calculations, forecasting and reporting enabling increased selling time
Improve leads to sales closure rates	Increase the percentage of leads which are converted to sales
Increase customer retention	Reduce customer churn rate and eliminate replacement expenses
Improve customer satisfaction and loyalty	Improve customer lifetime value

### 1) Tangible Net Benefits

A clear and precise cost-benefit analysis which tallies all of the planned project costs quantifies each of the tangible benefits and calculates key financial performance metrics such as ROI, NPV, and payback period.

### 2) Intangible Benefits

A total of the expected intangible benefits should include key performance indicators (KPI) that will be used to measure success or shortfalls of CRM project. These are a handful of areas of improvement that should be considered as Table 1 described.

### 3) Risk Assessment

Risk Assessment is also essential for CRM project success, because the evaluating the risks of people, process, and technology can proactively mitigate their probability and manage their impact on project success.

## 3. TCO AND ROI ANALYSIS OF CRM PROJECT

A survey of trends in the evaluation and purchase of CRM systems, released by Sage CRM Solutions, indicates that return on investment, cost and functionality are the three top issues for companies in the small to mid-market. Integration also figures significantly. However, ROI ranked as most important issue when evaluating CRM solutions.

We can get such conclusion, that ROI is the ultimate indicator of the success of a CRM program.

### i. The Control of TCO

The first benefit is Total Cost of Ownership (TCO). When implementing a CRM technology, the initial costs of licensing, hardware, software, training and consulting, along with the ongoing costs of support and maintenance, all play a role. In the past the failure to account for all of the implementation costs helped lead to CRM failures. Today, smart companies are working with vendors to keep

TCO to a minimum. The lower the TCO, the quicker a company can begin realizing ROI on its CRM investment.

### ii. The Enhancement of ROI

ROI from CRM typically comes in two forms: the first is cost reductions from increasing efficiency and the second form of ROI is revenue enhancements.

Through segmenting the different management layers, the main factors which have great influence on the ROI are described in the following text.

#### 1) Strategic layer

The way to realize lower TCO and higher ROI should include the following strategic imperative.

- Develop overall strategic plan that leverages the customer base as a valuable asset and grows that asset over time.
- Differentiate customers according to their value to the firm and their individual needs, and set a plan to focus resources on top customers.
- Provide strong executive leadership through ongoing visibility and reinforcement of customer-focused goals and rewards.
- Commit to organizational change across the enterprise in order to communicate strategic objectives, spark adoption and instill processes.

#### 2) Technology layer

Technology selection and framework will determine the success or failure of the CRM project, so that technology imperatives should be as following:

- Create a cross-functional team to define technology needs up front, prior to investment.
- Establish a strong relationship with a credible vendor capable of meeting your business needs and goals while keeping the initiative on time and on budget.
- Develop an integrated, scalable technology framework able to grow with the company over time.
- Match technology to processes built around the customer in order to empower customer facing-personnel and drive interconnected business long term.

#### 3) Analytical Layer

##### a) Cost reductions

Analytical CRM solutions decrease costs by enabling the organization to:

- Target campaigns more accurately to tightly defined customer segments instead of large, scattershot efforts.
- Reduce customer support requirements by offering products/services that better suit their needs.
- Eliminate products and services that fail to meet customer expectations.
- Reduce the cost of acquiring new customers, by getting more bites for the buck on marketing efforts and doing a better job of retaining customers.
- Tailor interactions differently to high-value and low-value customers by focusing more expensive communication channels and/or more attractive offers

where the payback is higher.

#### b) Revenue Enhancements

Analytical CRM solutions increase revenue by enabling the organization to:

- Cross-sell and up-sell more effectively. It is easier and less costly to retain existing customers than to attract new ones; therefore, organizations can realize greater profits by increasing revenue from existing customers rather than relying on all revenue growth to come from new customers.
- Predict which customers are most likely to buy, by recognizing that customer needs and wants are constantly changing based on multiple factors, such as life transitions, major milestones or acquisitions, external events and more.
- Identify high-value customers and cultivate long-term relationships, by focusing on the top 5 percent of the customer base that very well might account for 75 percent of revenues, and in the process, increasing the percentage of high-value customers.
- Increase brand awareness by providing well-targeted communications that will be well received, and by providing consistent customer treatment — a uniform company image — across all customer touch points.
- Increase customer satisfaction, loyalty and referrals by using the customer insights generated by analytical CRM to differentiate the organization from the competition with customer-pleasing actions, offers, products and services.

#### 4) Operational layer

##### a) Cost Reductions

In the following field we could realize the cost reductions:

- Service and Contact Center: reduced talk time, reduced post-call handling time, fewer call transfers, reduced wait times
- Sales: shorter sales cycle time, reduced cost of sales, less down time
- Marketing: reduced number of campaigns to cold prospects, fewer duplicate records and reduced levels of inaccurate customer data

##### b) Revenue Enhancements

In the following field we could enhance the revenue:

- Service and Contact Center: improved cross-sell and up-sell rates, higher problem resolution, higher customer satisfaction and re-purchase
- Sales: higher lead-to-close ratio, increased margins, more targeted and productive visits
- Marketing: improved response rates, increased number of annual campaigns, higher number of quality leads, increased average order size.

## 4. CAUSES OF HIGH FAILURE RATE OF CRM

Here we summarized some important reasons caused high failure rate of CRM implementation.

### i. Strategic Problem

#### 1) Implementing before creating strategy

A surprising number of firms dive headlong into CRM without carefully working out an exact customer strategy that the technology helps the company execute. Before even considering a specific CRM technology, organizations should figure out where they are going. This would include such basic planning actions as segmenting customers from most to least profitable, deciding whether to simply invest more in profitable customers, manage costs better to improve overall margins, divest unprofitable customers, or a combination of various options.

#### 2) No long-term strategy

Believing that CRM is a technology solution is still a tremendous obstacle for far too many firms. The fact remains that CRM is a business process change, often supported by technology. But there continues to be a tendency to look to technology as a sort of business panacea. Business leaders who do so are often disillusioned by CRM, because they don't align their business processes to meet specific goals.

#### 3) Lack of guidance

Companies would never construct their offices without a blueprint. According to Gartner, however, more than 60 percent of companies that have implemented CRM did not have mutually agreed upon goals for their projects prior to the installation. Like a building without a bearing wall, a CRM initiative without goals will collapse.

#### 4) No risk assessment or contingency plan

### ii. Organizational And Management Problem

#### 1) Lack of communication between IT and the business, resulting in a mismatch of requirements and expectations

#### 2) No senior business sponsor AND separate project manager

#### 3) Lack of employee support

It's natural to resist change. Top salespeople may ask, for example, why should we be forced to change our working habits, when those very habits helped us become so successful? On the other hand, poorer performers may fear the outcome of their managers having a window into their bad habits. Failure to convince these and other employees of the benefits of CRM often results in passive resistance and low employee-adoption rates.

#### 4) Technology put before people

No or minimal involvement of key users during the scoping phase and lack of regular communication with them throughout the project implementation.

#### 5) No accountability

Driven by fear of the unknown, resistance also spills into the managerial level in the form of avoidance, or lack of accountability. But CRM success depends on that accountability. The fact is, if accountability is not taken at the upper most managerial level, negligence there will only breed negligence among those who should be using the system, but aren't, making failure inevitable.

#### 6) Organizational culture is not aligned with the customer

Often management gives lip service to the notion of customer as king, but doesn't act that way. Workers are told to "delight the customer" but are actually rewarded for pushing peak volumes of product out the door, without regard for customer satisfaction. This type of company tends to overemphasize product metrics — such as inventory, costs and profitability — instead of customer measures, such as customer satisfaction, complaint levels, response times, loyalty, attrition and lifetime value.

#### 7) Restricted marketing scope

The current CRM practice restricts its marketing scope within a company's database. These companies concern more and more about the data in their databases, but pay less and less attentions to their market competitions and marketing potentials, especially the potential customers NOT yet in their databases. These companies lost their visions to their markets and their marketing basically becomes a sub-function of their IT department.

### iii. Customer Process Problem

#### 1) Installing CRM in an organization that isn't already customer focused

It is no wonder a large percentage of CRM failures stem from insufficient change management based on trying to force CRM down the throats of staff that don't yet have a customer focus or an organization that's processes are not conducive to the building of strong customer relationships. It is folly to embark on CRM without taking the time to survey the company then reconfigure all processes and systems so they actually fulfill customer needs.

#### 2) Incorrect definition of customer relationship

The current CRM practice incorrectly defines customer purchases and contacts as customer relationship. But customer purchases and contacts are the tangible customer behaviors rather than the customer relationship that drives these behaviors. Until it understands the driving force behind customer loyalty behaviors, a company is unlikely to be able to manage its customer relationship properly.

#### 3) Confusing customer interaction with hounding

In some cases, organizations have implemented CRM in such a way as to hound customers with repeat messages by phone, fax, email or direct mail. While marketing has used CRM to devise innovative methods of inundating the mailing list, this approach may actually drive business

away in the long run. The important thing is to identify the right customers i.e. those that actually want to form a relationship with you. Next, you have to work out how to contact them in the best way so that they continue to value the relationship.

#### 4) Ignorance of customers' needs

The current CRM practice lures companies away from their markets and their customers. The current CRM practice requires companies to focus on things like the correlations between product purchases for cross/up selling and the predictions of what customers will buy in the future from the products/services in their databases. So the companies that adopted the CRM practice tend to ignore their customers' real needs, which are the real drivers behind the purchase correlations.

### iv. Project Problem

#### 1) Poor project scoping and undefined project objectives, roles and responsibilities

These will lead to the setting of unrealistic expectations.

#### 2) No project success metrics

Without project success metrics CRM implementer can't efficiently monitor and evaluate the project under construction, so that enterprises are not able to guarantee the success of CRM projects.

#### 3) Lack of regular checks to ensure the project is on track - to time and budget

The direct aftermath of lack of regular checks to ensure the project is on track - to time and budget is that implementer of CRM can't strictly control the end time of accomplishment of CRM project with acceptable budget.

### v. Technology Problem

#### 1) The technology gap

Three key limitations typically undermine systems that support analytical CRM strategies:

- Organizations don't have an enterprise-wide view that reconciles and exploits data from all relevant functional/transactional systems across business units.
- Organizations may have simple analytics that tell them what was and what is, but not an accurate view of what will be, why and what to do about it.

#### 2) Solving CRM implementation problems with more CRM technology

Some companies try to implement a state-of-the-art CRM system at once. They spend, and often waste, millions in doing so. Their faulty reasoning considers that the latest technology will instantly solve a decade's worth of people problems that plague the business. More often than not, the expensive technology goes largely unutilized and the same problems continue to haunt the company. In many cases, then, it may be better to start small with a relatively

low-tech approach to CRM.

### 3) Integration Woes

Today there is no killer application that solves all integration problems. Most large-scale implementations require some customization. This may lead to problems that put vendors and consultants at odds with customers.

Many vendors and consultants maintain that most customers expect integration to happen like plugging a light fixture into a socket and flipping a switch, when in fact it is an evolutionary process.

### 4) Dirty Data

An often-overlooked, yet insidious hurdle is dirty data, or inaccurate and old information. Data is the lifeblood of a CRM system, and incorrect numbers, spelling mistakes, and outdated contact information can infect that system if it is left unchecked.

## 5. SUCCESS FACTORS IN CRM

The benchmarking consortium detailed and prioritized measurements for each benchmark identified in the kickoff meeting and guided the entire selection of successful practices. Our analysis led to the formulation of six success factors.

### 1) Evolution Path

As a first step, most companies implemented a system for operational CRM, e.g. call center or sales force processes. Analytical CRM rests upon this foundation and covers data mining and churn analysis functionality. Only little use was made of collaborative CRM which indicates an evolution path from operational, analytical to collaborative CRM and a stepwise implementation of CRM.

### 2) Timeframe

Most successful practice organizations have gone through a rapid system evaluation phase and completed the system introduction phase within approximately 7 months. But a full CRM was considered to take a minimum of 2 years. Successful companies split these long-term CRM projects into manageable subprojects lasting a maximum of 6 months.

### 3) Organizational Redesign

Prior to the introduction of a CRM system all successful practices established CRM concepts for the definition of processes and organizational structures. Organizational redesign also needs to consider structural issues, i.e. to establish a centralized responsibility and authority for defining cross-functional standards.

### 4) System Architecture

Virtually all the CRM systems in the benchmarking were standard packages, while no system offered a comprehensive operational, analytical and collaborative CRM functionality. Advanced CRM companies integrated specialized systems for operational, analytical, and collaborative CRM into a best-of-breed architecture.

Following the evolution path described above, mature CRM concepts also required integration architecture for seamlessly exchanging information.

### 5) Change Management

Convincing employees of the benefits of CRM methods and systems is regarded as an important success factor.

### 6) Top Management Support

For establishing customer orientation on a corporate level, implementing inter-organizational process and system standards, and for supporting the adoption of the CRM systems within the organization top management support was a key requirement. Top management sponsors also ensure that short-term setbacks in the CRM project can be overcome.

## 6. CONCLUSION

In order to do an ROI study correctly, we need enough customers with enough experience. What constitutes enough customers is the first problem. The validity of the sample is the next problem. The third problem is that even if you get a lot of ROI data from a lot of customers, it's rarely in a form that can be used to build a generalizable model. Every company had a different way to measure ROI.

Because of above-mentioned problems we have not tried to construct a generalizable panacea model, but only proposed criteria and critical factors to take account of during evaluating the RIO of CRM implementation of enterprise. There is very close linkage between the enhancement of ROI and the success rate of CRM implementation. If we pay enough attentions to success factors in CRM and avoiding causes of high failure rate of CRM projects, the ideal level of ROI must be reachable.

## ABSTRACT

In this paper, the author applied the concept of the Markov chain and divided sales procedures into several indexes and states; use the state index for connecting success in sales and customer relations into Pfeifer's method, establish a mathematical model, and demonstrate its result. In order to increase profits and decrease the cost of sales for the company, we further classify customers and propose different sale strategies. Case study and analysis are provided to elaborate the approach and its contribution to sales and CRM (customer relationship management) strategy.

Keywords: CRM, Relationship model, Selling process, Markov Chain

## 1. INTRODUCTION

Customer relationship modeling is always a popular topic for research. Sheng Peng conducted a thorough analysis, from the aspect of psychology, on the "customer person" in the process of selling.

He<sup>[1]</sup> considered that the selling is sales to people- to key customer people (KP, who are responsible for or have a direct controlling relation with the purchasing), no matter to a plant or a family. In the case, a selling is involved several factors, besides the enterprise's "selling points", customer's "purchasing point", more important, a good salesperson should also supply a KP with some "selling points" in KP's group, those selling points should be not only accepted by the KP from his heart, but also can be accepted by KP's group members, even more, some of the key ideas may let the KP believe the purchasing can bring him more respect in his group, and the KP is willing to declare the purchasing suggestion in the public. In such cases, the selling will be success in very large probability. He also thought that a sales process should be able to measured, it should never be managed in a "black box", managers can't handle the sales process and know the result only when it is out from the other side of the box. Such things happen because there is no state index set in the sales process, Sheng set up three indexes to help solving the problem.

Also to solve the problem, Reichheld, F.F.<sup>[6]</sup> consider that only one index is needed: "You simply need to know what your customers tell their friends about you". Morgan<sup>[7]</sup> and Kristensen<sup>[8]</sup> do not agree with his idea.

With regard to the customer relations mathematic model and the aspect of analysis, though many papers involving in the topic, most of them are methods based on the contacting and sales result information analyzing, only a few of them are modeling inside the process. Blattberg and Deighton<sup>[2]</sup> proposed an LTV(Life Cycle Value) model to compute the cost of acquiring and

maintaining customers. In order to help managers to optimize their sales, Bronnenberg<sup>[3]</sup> made an attempt to model and analyze consumer relationships using the Markov chain (MC); Based on supposed several states, Pfeifer and Carraway<sup>[4]</sup> constructed several CRM models with MC, and computed and analyzed different sales strategies within given parameters with profit as the objective, but they do not given more detailed computing and analysis to their model, also omitted that the supposed states can help salespeople improve their work; Jain and Singh<sup>[5]</sup> conducted a thorough survey of the area, describing the current and future trends.

In this paper we will introduce Sheng's indexes and apply the indexes into Pfeifer's<sup>[4]</sup> Markov model, then adopt different sales strategies, and a little detailed computing, to test the model, and analyze the benefit to the enterprise. In the analysis the customer classifying method will be employed, the results computed, and various scenarios compared.

## 2. THE SALES STATE INDEX, SELLING PROCESS, KNOWLEDGE, AND MARKOV MODEL

### 2.1 The Sales State Index, Selling Process Classification and Knowledge Management

In order to measure a sales process, Sheng<sup>[1]</sup> set up three index sets, based on the relationship between salesperson and KP, from connection relation, attitude to product, and confidence to product sides. Each index and states are given as following:

Connection index (To customer): Has nothing to say (low), and only says the official words (middle), the conversation is valid (good), and no secrets are kept from each other (high);

Attitude index (To product): basically not approve the product(low), basically approve the product(middle), and approve the product very much (high)

Confidence index (To product): approval given on a

case-by-case basis (low), approval given with appropriate examination (middle), approval given in big or important situations (high).

Such indexes are index with "operating concept", they can not only help salespeople make sure their sales state, but also supply them with an improved direction. For example, if your state is three "high" in the three sides, the selling will be success in very large probability; If your state is three "middle", it is hard to say your sales result, what you should do is to improve your relation with KP, in the three given sides, in order to get better state and have larger sales success probability; If your state is three "low", you can get success, but in a small probability.

Not as a traditional CRM system, the system built with such concept aims the data on KP's information, customer purchasing point (PP), sales point in his group (SP), customer views on criteria (VOC) and so on. Such indexes classify a whole sales process into states, and its operating concept about states normalize salespeople's sales state description and unify salespeople's understanding to each given sale state; make sales managers monitor his people selling easily; locate the state and direct the further improvement direction, and so on. Under such concept, we notice that a customer is not just a customer, but a separated decision process. Its system is a special knowledge management system, what it stores is "human" intelligence and analysis result, not just sales results, because its unified state description makes such management possible. With such system, enterprise managers and researchers can classify customers not only from sales result data, but also from the KP's character, PP, SP, and VOC, they can get more deeper and wider customer information, and what they get is the reason, not a statistical estimation, why customer buy or not buy their product. So such system can help the enterprise manage, share, accumulate, its salespeople's sales knowledge and key customer information. We think that a system built with such concept should be a real customer knowledge management system (more detail information can be seen from Sheng<sup>[1]</sup>).

## 2.2 Markov Chain Modeling

Based on the concept given above, we can discuss several sales strategies, when we separated a sales process in to several states, each with its sales success probability. Which scenario will be better, selling in large probability or selling in any chance? Following is the discussion by means of Pfeifer's MC model<sup>[4]</sup>. In order to simplify our discussion, we enlarge one of those index sets and use it to model the state of a sales

Fig 1 A sale procedure with given sale states

process. The confidence index set divides a sales process into the following five states: 5(former customer), 4(no approval in one-on-one situations), 3(approval in one-on-one situations), 2(approval in small catcall situations), 1 (approval in big or important situations). Obviously, state 1 holds the greatest probability of success. These relation states within a sales process are shown in Fig.1.

Pfeifer's model<sup>[4]</sup> is a model of the relationship between the sales and its customers (we set states following the thought). When the trading began, the relationship between the salesperson and the customer can be in any state in Fig.1, and the sale can be successful in any state, but the probability is different. Suppose the income of a successful sale is  $N=40$ , and the cost of the sale is 4. The probability of one sale succeed is the corresponding  $p_i$ . If the sale succeeds, the enterprise will obtain the benefit of  $N-M$ ; if not, the enterprise will lose  $M$ , and the probability of the relationship going back one state is  $1-p_i$ . Obviously,  $p_i < p_{i-1}$ ,  $p_i=1$ ,  $i=1,2,\dots,j$ , with  $j$  as the state number, state 5 indicating no connection. Suppose also that the cost of the sale is entered just before the deal is made.

The matrix  $P$  is a one-step transition matrix,  $R$  is a reward vector,  $V$  is the expected net present value<sup>[4]</sup>.

$$P = \begin{bmatrix} p_1 & 1-p_1 & 0 & 0 & 0 \\ p_2 & 0 & 1-p_2 & 0 & 0 \\ p_3 & 0 & 0 & 1-p_3 & 0 \\ p_4 & 0 & 0 & 0 & 1-p_4 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad R = \begin{bmatrix} N-M \\ -M \\ -M \\ -M \\ 0 \end{bmatrix} \quad V = \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \\ 0 \end{bmatrix}$$

Here  $M_1=M_2=M_3=M_4=M$ . In fact, the element of probability in the transition matrix (including in the result matrix  $P^2$ ,  $P^3$ ,  $P^4$ , etc.) represents the corresponding relationship between enterprise and customer after one or more sales. If required, we can set some threshold value or make hypothesis test to those elements which alert their relationship in case a problem occurs or the relationship is broken.

To be more precise, suppose that there is a discount rate to the present value after each purchase. Here, the discount rate is  $d=0.2$ . Thus, the expected net present value vector in  $j$  time of the sale, is(1):

$$V^j = \sum_{i=0}^{j-1} [(1+d)^{-i} R] = I * R + [(1+d)^{-1} P] R + [(1+d)^{-2} P^2] R + \dots + [(1+d)^{-j} P^j] R$$

In order to simplify the results, we often use an infinite horizon to describe the purchase. From (1), we can get the expected net present value as follows:

$$V = \lim_{j \rightarrow \infty} V^j = [I - (1+d)^{-1} P]^{-1} R \quad (2)$$

Supposed  $i=4$ ,  $p_1=0.3$ ,  $p_2=0.2$ ,  $p_3=0.15$ ,  $p_4=0.05$ , then:

$$V^4 = [50.115 \quad 4.22 \quad 0.592 \quad -1.98 \quad 0]^T$$

$$V = [52.32 \quad 5.554 \quad 1.251 \quad -1.82 \quad 0]^T \quad (2')$$

The result shows that, in this case, 25% customer (in state 1) makes the 90% profit of the enterprise. The negative expected value  $-1.98$ , in state 4, means sales enterprise shouldn't sell in such customer relationship,

because the success probability is too small. How to solve the problem? Classifying customer is one way to improve the condition.

### 3. CLASSIFYING ANALYSIS

The purpose of the analysis is to determine the profit of the sale enterprise, and the object of the research is to see the effect produced by different sale strategies adopted to different customers, after having divided customers into different types. In many cases, the sale enterprise does not hope to gain much from the first or second trade, but hopes to make money over a given period of trading. Therefore, for ease of analysis, we assume an infinite case for the sale. In this case, the negative value in the V vector of equation 2 means that if the first connection with the customer is at the corresponding state, no profits can be obtained from the sale even if the customer makes an infinite number of purchases. This is because the success rate in the state is too small or the sales cost is too high, relative to its income. We also transform equation 2 into 3 in the following analysis, to avoid the computation of d and the inverse operation in equation (2). We then have:

$$[I - P]V = R \quad (3)$$

Though there are 5 states in Fig.1, from the perspective of sales, there are only two kinds of customers: relationship and no relationship customers (or former customer<sup>[4]</sup>).

#### 3.1 Sales Strategies for Two Kinds of Customers

##### 3.1.1 The General Result for the Two Kinds of Customers Scenario

From equation (3), the sale enterprise's expected net present value equation is:

$$\begin{bmatrix} (1 - \frac{p_1}{1+d})v_1 - (\frac{1-p_1}{1+d})v_2 \\ (\frac{p_2}{1+d})v_1 + v_2 - (\frac{1-p_2}{1+d})v_3 \\ (\frac{p_3}{1+d})v_1 + v_3 - (\frac{1-p_3}{1+d})v_4 \\ (\frac{p_4}{1+d})v_1 + v_4 \\ 0 \end{bmatrix} = \begin{bmatrix} N-M \\ -M \\ -M \\ -M \\ 0 \end{bmatrix} \quad (4)$$

$$\text{then } \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \end{bmatrix} = \begin{bmatrix} v_1 \\ (\frac{p_2}{1+d})v_1 - M + (\frac{1-p_2}{1+d})v_3 \\ (\frac{p_3}{1+d})v_1 - M + (\frac{1-p_3}{1+d})v_4 \\ (\frac{p_4}{1+d})v_1 - M \end{bmatrix} \quad (5)$$

the result :

$$v_1 = \frac{N - (\frac{p_1}{1+d})v_1 - (\frac{1-p_1}{1+d})v_2}{1 - \frac{p_1}{1+d}} \quad (6)$$

therefore :

$$v_4 = \frac{N - (\frac{p_4}{1+d})v_1 - M}{1 - \frac{p_4}{1+d}} - M$$

among them :

$$p_i = \frac{p_i}{1+d}, q_i = \frac{1-p_i}{1+d}, p_i q_i = \frac{1}{1+d} \quad (i=1,2,3,4).$$

- z From equation (4) and (2'), we notice that the response of customers in different states to same input M is very different,  $p_1=0.3$ , and  $p_4=0.05$ . From Markov chain's concept, we can see customers in state4 as one time purchasing customers (OTPC), and ones in state1 as familiar ones. In order to compare easily, supposing we can increase sales cost to promote OTPC's success rate, to think it as linear relation simply,  $M_4 = (p_1/p_4)M$ , the result shows, in one side, the cost to acquire a new customer is as much as  $(p_1/p_4)$  times to retain a familiar one.

- z From equation (5), we can get:  $v_1 > v_2 > v_3 > v_4$ .

For:  $v_4 = p_4 * v_1 - M$ ;

$$v_3 = (p_3 * v_1 - M) + q_3 * v_4 > (1 + q_3) * v_4;$$

$$v_2 = (p_2 * v_1 - M) + q_2 * v_3 > v_3$$

$$v_2 < (p_2 * v_1 - M) + q_2 * v_1 = (p_2 + q_2) * v_1 - M < v_1$$

The  $v_2$ 's first item is  $p_2 * v_1$ , so  $v_1 > v_2$  and  $v_3, v_4$ , when  $p_2$  is small.

That means, under the given suppose, the better the relation is, the more the selling gets. The best relation customer will supply most of the sales profit.

- z If the aim is to obtain greater benefits,  $\sum v_i = \max$ , at least, each  $v_i \geq 0$  ( $i=1,2,3,4$ ). From (5), each  $v_i$  is related to its  $p_i$ , and in this case,  $p_4$  is the least, so if  $v_4 \geq 0$ , then other  $v_i \geq 0$  ( $i=1,2,3$ ). From (6), we can get the threshold  $p_4$  and M as following:

$$p_4 \geq \frac{M(1 - p_1 q_1 p_1 q_2 p_1 q_3 p_1 q_4 p_1 q_5 p_1 q_6 p_1 q_7 p_1 q_8 p_1 q_9 p_1 q_{10})}{N M (1 + q_1 q_1 q_2 q_3 q_4 q_5 q_6 q_7 q_8 q_9 q_{10})}$$

$$M \leq \frac{N p_4}{(1 + q_1 q_1 q_2 q_3 q_4 q_5 q_6 q_7 q_8 q_9 q_{10}) * p_4 + (1 - p_1 q_1 p_1 q_2 p_1 q_3 p_1 q_4 p_1 q_5 p_1 q_6 p_1 q_7 p_1 q_8 p_1 q_9 p_1 q_{10})}$$

The Fig2 shows the relation between them, to the given data, the threshold  $p_4$  in (2') should be  $p_4 = p_4 * d = 0.09$ , so in (2'),  $v_4 < 0$ . By the same way, we can get each threshold  $p_i$  and M ( $i=1,2,3$ ).

##### 3.1.2 The Modified Strategy 1 for the Two Kinds of Customers Scenario

Under the given condition, Sales enterprise should modify its sales strategy to avoid losing money. The

Fig 2 The relation between threshold  $p_4$  and M  
modified strategy 1 is to take no sales action to custom-

ers in state 4, and treat them as no relation customers.

Fig. 3 The state figure of Scenario (7)

When  $p_4 < M/v_1$ , in formula (5)  $v_4 < 0$ ; i.e. sales to customers in state 4 (no approval in one-on-one cases) can never yield a profit. So stopping sales to them and treating them as customers in state 5 is a new sales strategy (see Fig.3,  $p_4=0$ , the corresponding  $M=0$ ,  $V_4=0$ ). Putting those results to formula (5), we have:

$$V = [v_1 \quad p_2 * v_1 - M + q_2 * v_3 \quad p_3 * v_1 - M \quad 0 \quad 0]^T \quad (7)$$

Compared with formula (5), there is no negative  $v_4$  in  $v_3$ , which is in (7), so  $v_3$  in scenario (7) is better than that in (5); for the same reason, the  $v_2$  in scenario (7) is also better than that in (5). This means that, whether single  $v_i$  or total profit( $\sum v_i$ ) is involved, scenario (7) is better than that scenario (5). If  $v_4 > 0$ , the conclusion is different. Considered the (2') data, we have the result:  $V = [53.149 \quad 6.621 \quad 2.644 \quad 0]^T$ , it's better than (2').

The result means that enterprise should not sell in the very small success probability case.

### 3.1.3 Improved Strategy 2 for Two Kinds of Customers

Furthermore, we can take no sales action for customers in state 3,4, and to treat them as no relation customers, as our strategy 2.

Fig. 4 The state in improved Scenario (9)

Similar to the previous analysis (Fig.3, also suppose  $p_3=0$ , corresponding  $M=0$ ), taking the condition in formula (5), we get an improved scenario. In this case, the solution is:

$$V = [v_1 \quad p_2 * v_1 - M \quad 0 \quad 0]^T \quad (8)$$

Compared with formula (7), the scenario is better than that of (7) only when  $v_3 < 0$ . Otherwise, it will be worse than scenario (7), because, in this case,  $v_3$  can obtain profit. To the data given in (2'), we have result:

$$V = [51.574 \quad 4.596 \quad 0 \quad 0]^T, \text{ the result is not as good as (7), for the } p_3 \text{ in scenario (7) is great its threshold } p_3.$$

From the above analysis, we can see that the sales strategy is available, because the sales enterprise can gain greater benefits, in the case of its environment not changed.

### 3.2 The Sales Strategy for Multiple Types of Customers

The case in Fig.3 is not realistic enough, because the enterprise should put some money into improving its

relationships with its customer and bring it to a higher state: when the enterprise has made too few successful sales. Therefore, in order to reduce sales costs, we can divide both customers and sales costs into three types: sales cost  $M$ , retain cost  $H(<M)$ , and 0.

#### 3.2.1 Sales Strategy 1 for Three Kinds of Customers

A lower cost  $H$  is used for the case of improving customer relationships in order to reduce costs. Customers are classified into three types, such as 1,2,3;4; and 5; and the sales cost for state 4 is  $H$  (Fig.4). The difference with that of earlier is that current  $p_4$  is not the probability of making a successful sale, but the state of increasing one.  $v_i$  ( $i=1,2,3,4$ ) is still the present net value of each state. From equation (3), we can obtain the sale enterprise's expected net present value equation for the case of infinite purchases, as follows:

$$\begin{aligned} v_1 &= p_1 N_1(M) - (1-p_1)M \\ v_2 &= p_2 N_2(M) - (1-p_2)M \\ v_3 &= p_3 N_3(M) - (1-p_3)M \\ v_4 &= p_4 N_4(M) - (1-p_4)H \end{aligned}$$

The transition matrix  $P$  and reward vector is:

$$P = \begin{bmatrix} p_1 & 0 & 0 & 0 & 1-p_1 \\ 0 & p_2 & 0 & 0 & 1-p_2 \\ 0 & 0 & p_3 & 0 & 1-p_3 \\ 0 & 0 & 0 & p_4 & 1-p_4 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \quad R = \begin{bmatrix} N_1(M) - M \\ N_2(M) - M \\ N_3(M) - M \\ v_3 - H \\ 0 \end{bmatrix}$$

From equation (3), we obtain the expected net present value as follows. The symbols are the same as those in

$$V = \begin{bmatrix} \frac{(N_1(M) - M)}{1-p_1} & \frac{(N_2(M) - M)}{1-p_2} & \frac{(N_3(M) - M)}{1-p_3} & \frac{v_3 - H}{1-p_4} & 0 \end{bmatrix}^T \quad (9)$$

(6). Because formula (7) can be shown as following:

$$V = [v_1 \quad (p_2 + q_2 * p_3)v_1 - (1-p_2)M \quad p_3 * v_1 - M \quad 0]^T$$

and to prove which is larger((7) or (9)) is a little hard,

Fig.5 Comparing scenario (7) with scenario (9)

so we can deal with it by Fig.5 (with the data in (2')), the first three formulas are  $v_1, v_2, v_3$  in (7), and the fourth one(the line in the Fig middle) is the  $v_3$  in

scenario (9), the other two is:  $v_1 = 44.89$ ,  $v_2 = 40$ , when  $p_3$  varying from 0 to 0.4, so  $\sum v_i$  in scenario (9) is much better than that  $\sum v_i$  in scenario (7) (note: we haven't consider the  $v_4$  in scenario (9) in the analysis).  $V = [44.89 \ 40.00 \ 37.90 \ 49.47 \ 0]^T$  is the (9) result with the data in (2'), except  $p_4 = 0.3/1.2$ .

Fig. 6 The state in an improved Scenario (10)

The result means that enterprise should improve the relationship with customer first, and reduce the sales chance under too low success probability case.

### 3.2.2 Characteristics of the Transition Matrix

In a transition matrix with structure as such  $P$ , all customers will finally become no connection customers. Because when  $p_{ij} \geq 0$  in the matrix  $P$ , there must be a steady limit probability vector. Suppose this vector is  $W$  and that  $W = (W_1, W_2, W_3, W_4, W_5)^T$ . We then have a steady limit probability equation  $W = P^T * W$ . For the character of matrix  $P$ , we obtain the first two lines as:  $p_1 W_1 + p_2 W_2 = W_1$ . From the simultaneous equations,

$$(1 - p_1) W_1 = W_2$$

we have:  $p_2 W_2 = (1 - p_1) W_1$ . Because  $p_2 \geq 0$ , then,

$$W_2 = (1 - p_1) W_1$$

$W_1 = W_2 = W_3 = W_4 = 0$ ;  $\sum W_i = 1$ , so  $W_5 = 1$ .

The result means that a transition matrix with such a structure will result in decreased relationship as the trading time increases; finally, all customers will become no connection customers (steady state). The Pfeifer's calculation of  $P$ ,  $P^2$ ,  $P^4$  also shows similar characters<sup>[4]</sup>.

### 3.2.3 Sales Strategy 2 to Three Kinds of Customers

We can improve our sale strategy further, and propose a more conservative sales strategy: the enterprise should only conduct its sales in state 1, 2.

The sales enterprise may require a regulation that the product must be sold at the high relation state, i.e. where there is a high probability that the sale will be a success—in "approval in small catcall situations" and "approval in big or important situations." Therefore, by inputting  $H$  sales cost, each success in state 3, 4 can increase the step of the state forward by one state; each failure can set the relationship back by one state; and the sales action can only occur in states 1 and 2 with a cost of  $M$ . This strategy is exactly like the one that classifies customers into the following three types: 1, 2; 3, 4; 5, only now Fig. 5 is changed to Fig. 6. This is a typical random walk model. Hence, we can establish the equation by using formula (3):

$$\begin{aligned} v_1 &= N(M - p_1) - (1 - p_1)M \\ v_2 &= p_2 N - M - (1 - p_2)M \\ v_3 &= p_3(2 - H) - (1 - p_3)H \\ v_4 &= p_4(3 - H) - (1 - p_4)0 \end{aligned}$$

The transition matrix  $P$  and reward vector are:

$$P = \begin{bmatrix} p_1 & 0 & 0 & 0 & 1-p_1 & 0 & 0 & 0 \\ 0 & p_2 & 0 & 0 & 0 & 1-p_2 & 0 & 0 \\ 0 & 0 & p_3 & 0 & 0 & 0 & 1-p_3 & 0 \\ 0 & 0 & 0 & p_4 & 0 & 0 & 0 & 1-p_4 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad R = \begin{bmatrix} N-M_1 \\ N-M_2 \\ v_2-H \\ v_3-H \\ -M_1 \\ -M_2 \\ -H \\ 0 \end{bmatrix}$$

The expected net present value is equation (3) after the purchase (Suppose  $M_1 = M_2 = M$ ).

$$V = \begin{bmatrix} \frac{(N-M)M}{1-p_1} & \frac{(N-M)-q_2^*M}{1-p_2} & \frac{(v_2-H)-q_3^*H}{1-p_3} & \frac{v_3-H}{1-p_4} & 0 \end{bmatrix}^T \quad (10)$$

Comparing with scenario (9), there is no change in  $v_1, v_2$  of scenario (10). The value of  $p_3, p_4$  changes (the change will result in  $v_3$ 's numerator becoming larger and its denominator becoming smaller), but the change in  $v_3$  results in a change in  $v_4$ . If we can prove  $v_3$  in (10) is better than  $v_3$  in (9), then we can say scenario (10) is better than scenario (9). We have:

$$\frac{v_2 - (1+q_3)H}{1-p_3} - \frac{N - (1+q_3)M}{1-p_3} > \frac{v_2 - (1+q_3)M}{1-p_3} - \frac{N - (1+q_3)M}{1-p_3} = \frac{v_2 - N}{1-p_3}$$

Notice that, we use  $M$  instead of  $H$  for the comparing.

$$\frac{v_2 - N}{1-p_3} = \frac{\frac{N - (1+q_2)M}{1-p_2} - N}{1-p_3} = \frac{p_2 * N - (1+q_2)M}{(1-p_2)(1-p_3)}$$

When  $\frac{p_2}{1+q_2} > \frac{M}{N}$ , the  $v_3$  in (10) is better than  $v_3$  in (9).

Consider  $H$ , we can say that the scenario (10) is better than scenario (9). Also we can get result:

$$V = [44.89 \ 40.00 \ 51.64 \ 67.79 \ 0]^T$$

(Here:  $p_4 = p_3 = 0.3/1.2$ ), it looks better than that in scenario (9).

## 4. CONCLUSION

In the paper, we analyzed the customer relationship, set up the sales state index for the sales process, and modeled the relationship by introducing the concept of the MC based on the given state index; and presented the results of our analysis of the model. Pfeifer<sup>[4]</sup> pointed out that such an approach can also be applied to analyzing the problem of "Recency," "Frequency," and "Monetary."

The proposed approach here is to model the relationship with the MC by using various indexes, analyze the relationship between cost and the probability of making a successful sale in terms of benefits obtained, test different sales strategies on the model and present the corresponding solution.

The analysis results show us that the most conservative sales strategy is much better than the normal strategy.

That means, in the case of small sales success probability, the sales enterprise shouldn't sell in any state at any chance, but to improve the relationship with customer first and prepare to sell in the high success probability state.

## ABSTRACT

As auctions buyers and sellers become proliferated on the Internet, there are considerable interests in investigating consumer behavior in the new marketing context. Much of the research on online consumer behavior has focused on the economic dynamics of bidding and offerings, technical mechanism and privacy, while consumer trade-offs between auctions alternatives are still lacking in literature. The research objective of this paper is to examine how consumers evaluate each seller's attributes and make bidding decisions. A conjoint analysis was used to investigate subject's bidding intention and trust for a variety of used textbook sellers that differed in terms of bidding price, seller rating (feedback score), payment type, and shipping charge. This article provides an experimental test of consumer's trade-offs in online auctions context. These findings are essential because they help identify the importance of those attributes of online auctions under the consideration of bidding intentions and seller's trustworthiness. Interestingly, this paper suggests auctions sellers may succeed by simply compete on price. However, this conclusion could only be generalized in used textbook category; further research could include additional product categories as exemplars and different auctions attributes as factors. Although price and seller rating seem to be relatively more important factors, further research could examine factors in addition to payment type and shipping charge of the auctions.

**Keywords:** trade-off, online auctions, conjoint analysis, internet marketing

## 1. INTRODUCTION

In the past few years, online auctions have been the most profitable business model on the web. According to statistics reported by A.C. Nielson, online auction bidders grew three times over the past two years in Taiwan. Take the famous Internet auction site, eBay and Yahoo! Auction, for example, people visit the online auction marketplace to buy and sell items in thousands of categories including clothes, antiques, books, computers, DVDs, real estates, electronics & computers, etc. With huge arrays of choices, online auctions have not only changed the parameters of traditional auctions, but also provided the sellers with more degrees of freedom. The Internet provides consumers with multitude choices and convenience, at the same time, risks and uncertainties on the web are inevitably major concerns for buyers and sellers due to online anonymity and fraud threats.

Over the years auctions have become known as not only economic events, but also as socially and culturally significant affairs. As auctions buyers and sellers become proliferated and active on the Internet, there are considerable interests in investigating consumer behavior in the new marketing context. However, most of the research on online auction behavior focused on the dynamics of bidding and offerings, auction platform mechanism and privacy, while consumer's decision making for online auctions alternatives are still lacking in literature.

The research objective of this paper is to examine how

consumers evaluate each seller's attributes and make bidding decisions. In this paper, we examine subjects' preferences for a variety of auction alternatives that differ in terms of four major attributes, which are hypothesized to be important to consumer's bidding judgments and perceptions of seller trustworthiness, and compare how demographics and web experiences influence consumer's preferences.

In the following sections, we review the benefits of online auctions, and consumer's evaluation criteria that are used in this research. Then we develop hypotheses to explicate the factors that affect consumer's trade-off between attributes. We use conjoint experimental design to test the hypotheses, and the results will be reported. In the final section our conclusions of the study will be provided.

## 2. ONLINE AUCTIONS

### 2.1 Benefits of Online Auctions

As economic scholar Steve Kaplan (1999) of Chicago University pointed out that online auctions have greater economic advantages as compared to traditional auctions. Hanson (2000) contended that online auction sites improve the power and efficiency of auctions, because: (1) the Internet makes it easier to gather buyers and sellers together in the same place at the same time; (2) the Internet enables sellers to provide in-depth information, so buyers can evaluate the item being sold; (3) the Internet expands the number of bidders, which raises the price paid and the profitability of the auction.

Online auctions are very appealing from the viewpoints of both businesses and consumers. The auctions are a typical example of the ideal online business: they act as intermediaries between buyers and sellers; except for office space, they do not require extensive investments in physical property as well as inventory. For consumers, the online auctions websites offer access to tens of thousands of various goods around the world. On the other hand, the competitive nature of the online auctions' bidding processes enables sellers to achieve a better price than they might have using traditional media such as newspaper classifieds.

## 2.2 Attributes of Online Auctions

Although online auctions have many advantages for both consumer and seller as mentioned above, there are disadvantages that are obstacles for consumer to participate in an auction deal. First, there is the potential for fraud from dishonest or irresponsible sellers, which could cause buyer losses. Second, there are also concerns of financial privacy issues and personal information misuses. Third, consumer may have to accept undesirable restrictions because of failing to read the fine print. Fourth, products may not always be cheaper than a local store, especially when the cost of shipping is included.

To overcome the potential problems in online auctions, consumers have to evaluate the information given by sellers on the web, and make the decision. Our research goal is to examine how consumer tradeoff among different sellers under the consideration of bidding intention and seller trustworthiness for a given product. We select four attributes that are fundamental to consumer's decision making in evaluation of a seller under the context of online auctions. These attributes are price, seller rating, payment type, and shipping charges.

### 2.2.1 Price

The pricing mechanism is the most discussed issue in auctions. Increasing information on the web may lead to less willingness to pay. Common perception is that the Internet will raise consumer price sensitivity, especially when the websites enable instantaneous side-by-side price comparisons of available alternatives (Hanson, 2000). However, Preliminary research concerning the price of online items finds increased price dispersion (Brynjolfsson & Smith, 1999) with online prices often surpassing the price of similar products purchased through more traditional venues (Lee, 1997; Bailey, 1998). It remains to be seen if price competition significantly increases as electronic markets mature (Smith, Bailey & Brynjolfsson, 1999).

### 2.2.2 Seller rating

The most common type of consumer protection feature

offered by online auctions is a user rating service, in which buyers and sellers can rate each other based on how promptly product was received, how quickly a buyer provided payment, etc. These ratings are maintained on auctions' websites and are easily accessible by users. Auction participants can use feedback systems to publicly rate their satisfaction towards their trading partners. Specifically, the feedback system is a measure of a user's reputation in an auction community. The auctioneers encourage all users to check their trading partners' rating before transactions and leave feedback about their trading partners after their transactions. In essence, the system tries to use one's reputation as a deterrent for cheating behaviors. That is, if one develops a bad reputation, other auction participants may not transact with the person anymore (Ba, Whinston, and Zhang, 2003).

### 2.2.3 Payment type

There is a wide range of ways to pay on auctions websites, such as eBay or Yahoo, and most sellers offer more than one option. Some payment options offer more protection than others, so consumers are prompted to select a method of payment that makes them feel comfortable, especially when most of the auctions require buyers to pay in advance. There are three payment types that usually used in Taiwan, cash, bank transfer and credit card. In this study, we use these three options in the experimental design.

### 2.2.4 Shipping charge

For most of transactions on the Internet, payment and delivery rarely occur simultaneously. Notable exceptions exist where payment and delivery can occur nearly simultaneously for online purchases (e.g., when purchasing MP3 files). More commonly, the buyer is required to pay in advance for a product or service to be delivered sometime into the future, often with little or no ability to examine the product or service in advance. Specific shipping costs are noted in item descriptions approximately 50% of the time and almost every seller require buyers to pay for shipping and insurance fees (James H. Gilkeson and Kristy Reyonlds, 2003). From consumers' perspectives, shipping charges are additional costs occurred in auctions. Therefore, when making a bidding decision, consumers have to take these delivery costs and risks into account. In Taiwan, self-pickup is a common alternative to shipping services, so we include this option into this study.

## 3. RESEARCH HYPOTHESES

The goal of this study is threefold. The first one is to compare how consumer evaluate different sellers based on judgment of bidding intention and seller trustworthiness. The second is to understand how consumer trade-off between four auctions attributes. The third one is to examine demographic and web

experience affect consumer trade-offs. Accordingly, we propose and will test the following hypotheses:

H1: Consumer's preference for online auctions attributes will vary, depending on the type of evaluation (bidding intention and seller trustworthiness) being asked of the respondent

H2: In evaluated judgment of bidding intention, consumer's preference for online auctions attributes will vary, depending on the demographic variables and web experience of the respondent

H3: In evaluated judgment of seller trustworthiness, consumer's preference for online auctions attributes will vary, depending on the demographic variables and web experience of the respondent

#### 4. RESEARCH METHOD

##### 4.1 Subjects

There are 221 college students (122 men and 99 women), from two northeastern colleges in Taiwan, participated in this study, and their demographic variables and web experience variables were collected. The average age of the subjects was 21 years old, 44.3 percent of them had online auctions experiences.

##### 4.2 Experimental design

A conjoint analysis was used to investigate subject's bidding intention and trust for a variety of used textbook sellers that differed in terms of bidding price, seller rating (feedback score), payment type, and shipping charge. A used computer textbook with list price of NT\$800 was used as the product auctioned on the web. In this experiment design, subjects were asked to consider and make preference choices among hypothetical seller profiles, and decide on their bidding intentions and seller's trustworthiness. In this study, each seller profile had four attributes, i.e. bidding price, seller rating, payment type, and shipping charge, and each attribute had three levels as shown below,

- (1) Bidding Price: a. NT\$480, b. NT\$400, c. NT\$320
- (2) Seller rating: a. 650, b. 350, c. 50
- (3) Payment types: Cash (or money orders), Bank transfer, Credit card
- (4) Shipping charges: a. Buyer pays shipping (NT\$80 dollars), b. free of charge, c. self-pickup

Because a full factorial design for this study would require 81 ( $3^4$ ) profiles, an orthogonal fractional factorial design (of 9 profiles) was used to reduce the number of attribute combinations and thus make the task of decision making more manageable.

The experiment scenarios addressed were similar to that encountered in full-profile rank conjoint analysis; subjects were asked to give a rank order of preference

for the 9 full profiles constructed by using the orthogonal main-effect design as Table 1.

**Table 1 : Full profiles constructed by using orthogonal design**

No.	Price	Seller rating	Payment types	Shipping charges
1	NT\$240	350	Credit card	Buyer pays
2	NT\$240	50	Cash	Free of charge
3	NT\$320	650	Credit card	Free of charge
4	NT\$320	50	Bank transfer	Buyer pays
5	NT\$320	350	Cash	Self-pickup
6	NT\$400	350	Bank transfer	Free of charge
7	NT\$400	650	Cash	Buyer pays
8	NT\$240	650	Bank transfer	Self-pickup
9	NT\$400	50	Credit card	Self-pickup

Figure 1 is an example of profile card, and every respondent was given 9 profile cards to sort out his or her ranking.

<b>Seller No.1</b>
<b>Bidding price :</b> NT\$240 dollars
<b>Seller rating :</b> 350
<b>Payment types :</b> Credit card
<b>Shipping charge :</b> Buyer to pay shipment (Additional NT\$80 dollars shipment cost)

**Figure 1 : Seller No.1 profiles card**

#### 5. RESULTS

##### 5.1 Conjoint analysis

This research examined how various characteristics of auctions terms and the basis of consumers' evaluations affect their judgments about online auctions alternatives. The multivariate statistical method best suited for examining the trade-offs consumers are willing to make is a conjoint analysis. Conjoint analysis is a technique that requires subjects to make a series of judgments based on a set of attributes from which the underlying structure of their decisions can be decomposed. Conjoint analysis provides us with information about which attributes of an auction alternative are more important, and what trade-offs respondents are willing to make.

Table 2 shows the results of conjoint analysis. Bidding price is the most important attribute (28.60%) in respondent's bidding intention judgment; the next important factor is seller rating (25.25%); while payment type (22.41%) and shipping charge (23.73%) are relatively less important. Utilities of each attribute

level are also shown in the table. Figure 2 indicates the utilities of each level for four attributes. The utility lines of bidding price shows that consumer prefers low price, and there is an increase in the marginal utility from NT\$400-NT\$320 to NT\$320-NT\$240 price interval. Seller rating has positive correlation with respondent's utility, in a diminishing marginal utility form. In addition, bank transfer and free of shipping are most preferred in attribute of payment type and shipping charges.

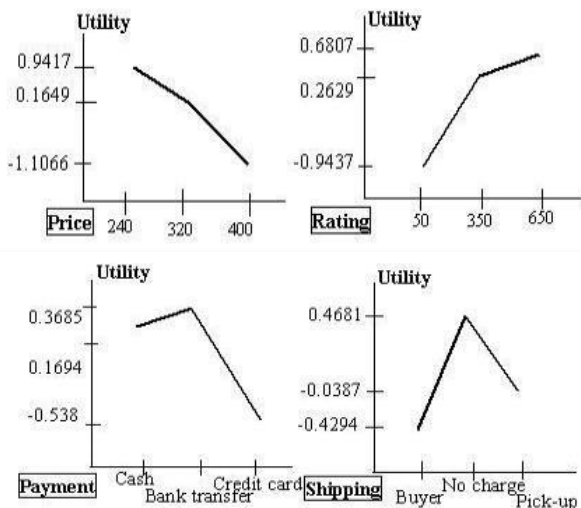

Figure 2 : Utility plot of four attributes in bidding intention evaluation

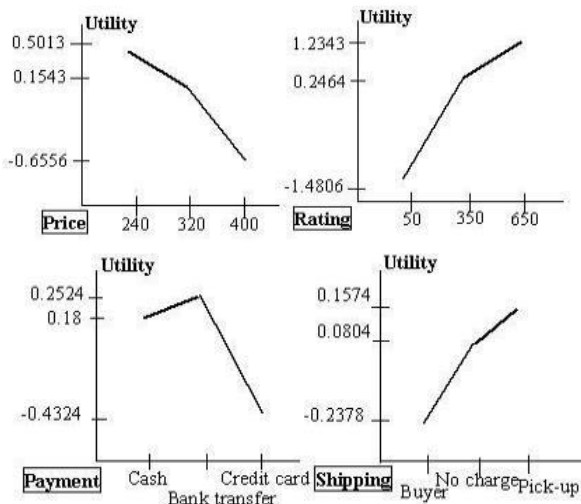

Figure 3 : Utility plot of four attributes in seller trustworthiness evaluation

When asked of seller trustworthiness, consumer weighs highly on seller rating (37.46%), while price (22.44%), payment type (20.26%) and shipping charges (19.84%) are far less important. Figure 3 shows the utility lines for each attributes. The only difference between bidding intention and seller trustworthiness evaluation is that respondents prefer self-pickup to other shipping charge options. The reason might be that self-pickup allows buyers to check the product before the deal is completed.

The results support hypothesis 1.

## 5.2 Test of H1

The data collected from respondent allow comparison of what online auctions attributes consumer desire when making judgment of bidding intention and seller trustworthiness. Since the two types of evaluations are within-subject data, we conduct a paired sample t test to examine whether the importance of each attribute is the same. The results show that the relative importance of bidding price ( $t=3.497$ ,  $p=.001$ ), seller rating ( $t=-6.838$ ,  $p=.000$ ), and shipping charges ( $t=2.696$ ,  $p=.008$ ) are significantly different, which means that when consumers consider of bidding for certain auctions, they focus on different auctions attributes than when they are asked to evaluate seller's trustworthiness. Table 3 shows that bidding price and shipping charge are weighed more when respondent intends to bid, while seller rating is significantly more important when respondent evaluate seller trustworthiness. Though seller rating might play an important role in consumer's bidding intentions, the results indicate that consumer's perceptions of these two concepts are quite distinct.

Table 2: Conjoint analysis of online auctions alternatives

	Level	Bidding Intention		Seller Trustworthiness	
		Utilities	Importance	Utilities	Importance
	NT\$400 NT\$320 NT\$240	-1.1066 0.1649 0.9417	28.60%	-0.6556 0.1543 0.5013	22.44%
	650 350 50	0.6807 0.2629 -0.9437	25.25%	1.2343 0.2464 -1.4806	37.46%
	Cash Bank transfer Credit card	0.1694 0.3685 -0.5380	22.41%	0.1800 0.2524 -0.4324	20.26%
	Buyer pays No charge Self-pickup	-0.4294 0.4681 -0.0387	23.73%	-0.2378 0.0804 0.1574	19.84%

Table 3: Paired sample t test for evaluation types

Attribute	Mean differences	St. error measures	t	p (2-tailed)
Price	5.8424	1.6706	3.497	.001
Seller rating	-12.0619	1.7640	-6.838	.000
Payment type	2.0519	1.4289	1.436	.152
Shipping charges	3.6361	1.3489	2.696	.008

### 5.3 Test of H2

In this study, respondents' demographic variables (such as sex and age) as well as web experiences (i.e. Internet experience, online purposes, Internet usage, online auctions experience, and spending online) were collected. We use ANOVA to test how these variables affect the preferences of each attributes when making evaluation of bidding intention. The results of this analysis are explicated in Table 4.

**5.3.1 Sex.** There is significant effect of sex on the preference of shipping charges ( $F=5.902$ ,  $p=.016$ ). Female respondents concern more on shipping charges ( $\bar{x}=26.44$ ) than male respondents ( $\bar{x}=21.46$ ) when being asked of bidding intention.

**5.3.2 Age.** Age has significant effect on both bidding price ( $F=12.514$ ,  $p=.000$ ) and seller rating ( $F=5.074$ ,  $p=.007$ ). The data indicates that older respondents are more concerned of bidding price, and less concerned of seller rating. Further analysis shows younger respondents are less price sensitive than older ones.

**Table 4: ANOVA for evaluation of bidding intention**

Attributes <sup>a</sup>	BP	SR	PT	SC
Sex	0.012 <sup>b</sup>	0.296	2.965	<b>5.902*</b>
Age	<b>12.514*</b>	<b>5.074*</b>	1.865	1.773
Internet experience	1.682	2.413	0.326	0.597
Online purpose	0.259	0.279	1.224	1.594
Internet usage	1.014	0.853	0.843	0.739
Online auctions experience	<b>10.838*</b>	<b>13.092*</b>	0.154	0.108
Spending online	<b>4.866*</b>	0.471	<b>3.344*</b>	1.562

Notes: numbers in cells are statistic F

<sup>a</sup> BP: Bidding price; SR: Seller rating; PT: Payment type; SC: Shipping charges

\* Significant at  $p<.05$

**5.3.3 Internet experience, online purpose, and Internet usage.** Preferences of online auctions attributes are not significantly influenced by Internet experience, online purpose, and Internet usage.

**5.3.4 Online auctions experience.** Bidding price is significantly more important to consumers with auctions experience online, and less important to ones without any online auctions experience ( $F=10.060$ ,  $p=.000$ ). On the other hand, respondents with auctions experience weigh less on seller rating than respondents without any experience ( $F=13.849$ ,  $p=.000$ ).

**5.3.5 Spending online.** Respondents' spending amounts online per month significantly affect their utilities of bidding price ( $F=4.866$ ,  $p=.001$ ) and payment type ( $F=3.344$ ,  $.013$ ).

### 5.4 Test of H3

The following analysis will use demographics and web experience as independent variables to test if the utilities

of each attributes are the same, when respondents are asked of seller trustworthiness evaluation. Table 5 shows that sex, web experience, and spending online do not have significant effect on auctions attributes. The effects of age, online purpose, and internet usage, and online auctions experience are reported below.

**5.4.1 Age.** There is significant effect on bidding price by age ( $F=8.079$ ,  $p=.000$ ). Younger respondents weigh more on bidding price for cues of seller's trustworthiness than older ones.

**5.4.2 Online purpose.** The purpose of online has significant effect on bidding price ( $F=3.088$ ,  $p=.028$ ). Consumers with online purposes of finding product information concern more on bidding price.

**5.4.3 Internet usage and online auctions experience.** Shipping charge is a significant important factor for intensive web users ( $F=3.155$ ,  $p=.025$ ) and experienced auctions consumers ( $F=7.252$ ,  $p=.008$ ).

**Table 5: ANOVA for evaluation of seller trustworthiness**

Attributes <sup>a</sup>	BP	SR	PT	SC
Sex	2.837	2.067	0.446	0.078

internet usage	1.012	1.232	0.476	<b>3.155*</b>
online auctions experience	2.639	0.635	1.248	<b>7.941*</b>
Spending online	2.393	0.478	0.218	0.710

Notes: numbers in cells are statistic F

<sup>a</sup> BP: Bidding price; SR: Seller rating; PT: Payment type; SC: Shipping charges

\* Significant at  $p<.05$

## 6. CONCLUSION

This article provides an experimental test of consumer's trade-offs in online auctions context. These findings are essential because they help identify the importance of those attributes of online auctions under the consideration of bidding intentions and seller's trustworthiness. The results indicate significant differences between the types of evaluative judgment. The findings indicate that the way consumer perceives trustworthiness of a seller is quite different from their bidding intention.

This research examined how various characteristics of auctions terms and the basis of consumers' evaluations affect their judgments about online auctions alternatives. Using conjoint analysis and ANOVA, we were able to examine subjects' utilities for sellers' offerings that differed along four attributes as well as how these utilities were affected by demographic variables and web experience variables. The results indicate that price is the most important factor in bidding intentions (relative importance: price 28.6%; seller rating: 25.25%;

payment type: 22.41%; shipping charge: 23.73%), whereas the seller rating plays a more important role in consumer's trust in online auctions (relative importance: price 22.44%; seller rating: 37.46%; payment type: 20.26%; shipping charge: 19.84%). Payment type and shipping charge are also important factors, since utilities for these two factors are significantly greater than zero. The demographic variables show some influences on the utilities, for instance, female buyers are more sensitive to shipping charges, and older consumers put more weights on seller's ratings. As for web experience, the more experienced consumers are more low-price prone, and have significantly different judgments as compared to less experienced ones.

Interestingly, this paper suggests auctions sellers may succeed by simply compete on price. However, this conclusion could only be generalized in used textbook category; further research could include additional product categories as exemplars and different auctions attributes as factors. Although price and seller rating seem to be relatively more important factors, further research could examine factors in addition to payment type and shipping charge of the auctions. Of course, further testing should go beyond the college student sample.

## Cross-Cultural Differences of Online Store Image Perception and Customer Purchasing Intention

Qinyu Liao, J. P. Shim

Dept. of Management and Information System  
Mississippi State University, Mississippi State, MS, 39762, U.S.A.  
ql15@msstate.edu<sup>1</sup>, jshim@cobilan.msstate.edu<sup>2</sup>

### ABSTRACT

In this study, seven factors affecting consumer perception of online store image are identified based on store image measurement of traditional stores. Enjoyment and trustworthiness are two new antecedents suggested for the online store image. A cultural dimension is also introduced to understand the possible differences of model structure and relationships between online store image perception, attitude toward purchasing at an online store and customer purchasing intention in a cross-cultural setting.

**Keyword:** Online store image, purchasing intention, cross-cultural difference

### 1. INTRODUCTION

Online shopping revenues and related corporate profits are still meager, though the industry is optimistic (Hoffman et al., 1999). Generating revenues using an online store is one of the key issues facing electronic commerce practitioners today.

Most studies of online shopping attitudes have attempted to identify factors influencing online shopping attitudes and behavior by taking different perspectives and focus on different factors in different ways. Store image is a multi-faceted construct that has been rigorously researched for "traditional stores". Several researchers have been able to successfully link "store image" to "intention to purchase" (Nevin and Houston, 1980; Grewal et al., 1998).

A significant number of online stores are designed and developed for firms with global reaching, but most of them address different cultural audiences with only linguistic difference (Chau et al., 2002). Studies have found cultural differences in using information systems (Nelson et al., 1992; Ho et al., 1989). Understanding cultural and national effects on the use and management of IT is vital for multi-national firms.

The purpose of this study is to explore factors affecting consumer perceived online store image and its effect on subsequent purchasing intention, and proposed that online store image dimensions and their effect on attitude towards online store and purchasing intentions differ cross-culturally.

### 2. THEORETICAL MODEL

As both the presence and operation of online store depend heavily on IT, they are often regarded as a type of IS. Hence, when consumers accept and use

online store, they are accepting and using technologies and innovations.

Derived from TRA (Ajzen and Fishbein, 1980), TAM (Davis, 1989) has been proven successful in prediction and explaining behavior across a wide variety of domains including IT usage. The model hypothesizes that actual system use is determined by users' attitudes toward using. Attitude is directly affected by beliefs about the system, which consists of perceived usefulness and perceived ease of use. Researches have successfully adopted TAM to study the acceptance of Internet related technologies, such as email (Gefen, 1997), the World Wide Web (Fenech, 1998), and E-commerce (Chai, 2002). Therefore, using it as the basis for studying consumer perception of online store image is a valid approach.

Although TRA has been tested cross-culturally, it has been criticized for assuming western perspectives on time orientation, probabilistic thinking and locus of control (Cote and Tansuhaj, 1989). The model best captures the scientific, abstracting, context independent nature of western thought, coupled with its extensive empirical validation among western samples (Eagly and Chaiken, 1993). To model intention formation and prediction, cultural impact should be considered by using measures that reflect culturally-sensitive operationalizations of the underlying latent constructs (Malhotra and McCort, 2001).

### 3. CONCEPTUAL DEVELOPMENT

The online store is "a storefront in cyberspace, a place where customers can shop from their home computers and where merchants can offer merchandise and services for a fraction of the overhead required in a physical storefront" (Yesil, 1997).

Store image is the “personality” the store presents to the public. Studies have identified dimensions consumers perceive stores, which collectively make up store image (Hirschman, Greenberg and Robertson, 1978). Dickson and Alba (1977) refined existing instrumentations for retail store image and ultimately arrived at the following dimensions: prices, products, store layout and facilities, service and personnel, promotion and “others.” Store image has been used as a predictor for numerous variables, including attractiveness of shopping area (Nevin and Houston, 1980) and purchase intention (Grewal et al., 1998). Creating or changing a shopping

area’s image is often a prerequisite to getting consumers to change their existing shopping intentions and behavior (Nevin and Houston, 1980).

The antecedents of an individual’s intention to purchase online store are likely to contain elements that are related to online store image. Jarvenpaa et al. have investigated empirically the relationship between intention to shop online, attitude towards shopping online and trust in the online store (Jarvenpaa, Tractinsky and Vital, 2000).

Online store image

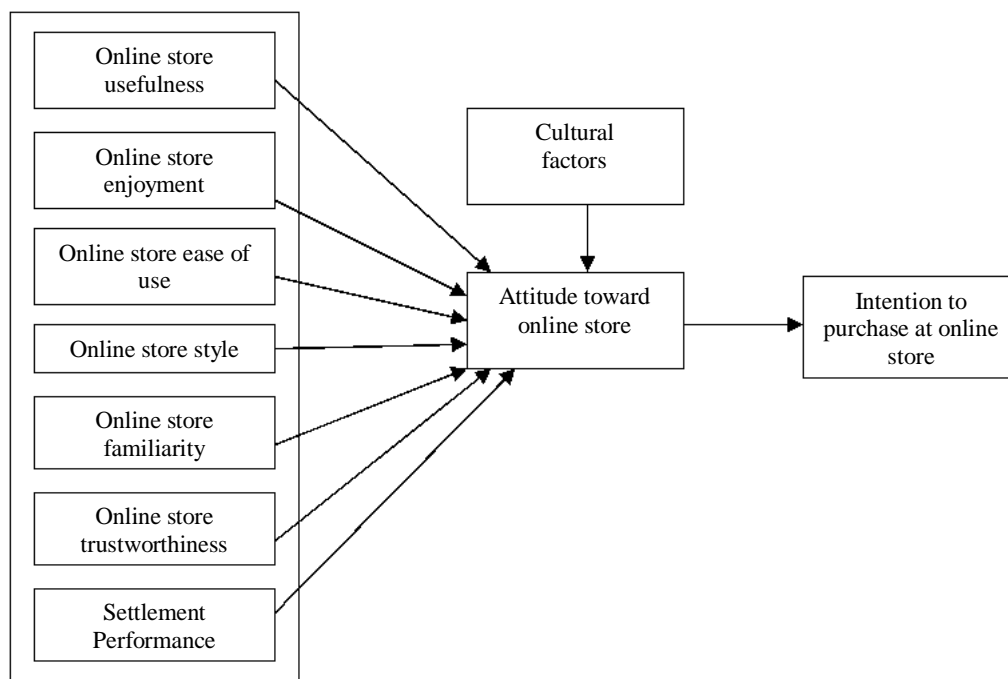

Figure 1. Research Model

Based on online store researches, seven factors that could affect consumer online store image perceptions are identified. They are online store usefulness, online store enjoyment, online store ease of use, online store style, online store familiarity, online store trustworthiness, and settlement performance. The research model in this study was developed based on TAM and these factors (Figure 1). A cultural dimension is added as the moderator.

### 3.1 Online Store Usefulness

Online store usefulness refers to the user’s subjective probability that using a specific online store will increase his or her performance in purchasing and information searching (Davis, 1986). The attributes include product variety, brands, price and product-retailing channel fit. The quality and usefulness of the information the customers found at the online store will

determine their prediction of satisfaction with the product prior to the actual purchase (Chen, 2001).

*Proposition 1: The usefulness of an online store positively affects a consumer’s attitude toward purchasing at an online store.*

### 3.2 Online Store Ease of Use

Online store ease of use is the degree to which a user expects the use of the target online store to be free of effort (Davis, 1986). Some of the attitudes are easy-understanding, easy-finding, easy-learning, information focus (Lederer et al., 2000), and time taken for navigation and page download (Ranganathan and Ganapathy, 2002).

Studies have found out that consumer computer experience and use of other in-home shopping methods

influence a consumer's propensity to purchase at an online store.

*Proposition 2: The ease of use of an online store positively affects consumer's attitude toward purchasing at an online store.*

### 3.3 Online Store Style

The online stores face the heterogeneity of user profile. An online store that can attract, sustain and retain customers should have friendly interfaces, pleasant information presentation, and personalizable and supportive information services, such as multiple versions for different connectivity, chat room and email.

The usage of colors, multimedia, animation and graphics can reach customers on multiple cognitive levels and result in higher retention (Ranganathan and Ganapathy, 2002).

Ducoffe (1996) notes that irritating banner ads may be perceived as an unwanted, offending, and negative influence.

*Proposition 3: The online store style positively affects a consumer's attitude toward purchasing at an online store.*

### 3.4 Online Store Familiarity

Online store familiarity refers to customer's recognition of products, brand names and store names (Grewal et al., 1998). The store name is a form of the category-based processing perspective of store image (Keaveney and Hunt (1992). Brand name is a commonly used extrinsic cue to infer quality perceptions and can represent an aggregate of information about a product and its quality (Richardson, Dick and Jain, 1994; Dodds et al. (1991). Online shopping is closely related to recognition and recall (Chao, Au and Tam, 2000). Exposure to the brand name or store name gives customers a certain degree of familiarity.

*Proposition 4: The online store familiarity positively affects a customer's attitude toward purchasing at an online store.*

### 3.5 Online Store enjoyment

Enjoyment/playfulness refers to the pleasant and fun experience a consumer have with an online store, such as the eye-catching dynamic banners, enlivening background music or other multimedia online broadcasting, chat rooms, and online games. Enjoyment/playfulness has been suggested as an important dimension of consumer attitude towards online store (Liu et. al, 2000; Koufaris et al., 2002). Ducoffe (1995; 1996) evidences that enjoyment is positively related to online store advertisement value

and attitude to online advertising, and has been empirically linked to attitude towards using a website (Heijden et al., 2001; Webster, 1992).

*Proposition 5: The online store enjoyment positively affects a consumer's attitude toward purchasing at an online store.*

### 3.6 Online Store Trustworthiness

Trust in an online store is the subjective probability by which consumers expect that an online retailer will perform a given transaction in accordance with their confident expectations (Chai and Pavlou, 2002). Trust gives the consumer trust beliefs that they will gain control over a potentially uncertain transaction. Consumers have not widely adopted e-commerce (Hoffman et al., 1999), primarily because of trust issues (Palmer, Bailey, and Faraj, 2000) related to online retailers who have the chance to behave in an opportunistic manner by taking advantage of the distant and impersonal nature of online stores.

Consumers would be hesitant to transact with an online store that fails to signal a sense of trustworthiness. On the other hand, trust creates positive feelings towards transactions with online stores, providing expectations for a satisfactory feeling towards transactions with online stores, providing expectations for a satisfactory transaction. High-involvement goods, such as pianos, mortgages and intercontinental flight tickets, are likely to have a more severe impact on the relationship between trustworthiness and attitude to purchase (Heijden and Verhagen, 2002).

Jarvenpaa et al. (2000) discovered that higher consumer trust also reduces perceived risks associated with Internet shopping and generate more favorable attitudes towards shopping at a particular store, which in turn increases willingness to purchase from that store.

*Proposition 6: The online store trust-worthiness positively affects a consumer's attitude toward purchasing at an online store.*

### 3.7 Settlement Performance

This is a construct first introduced by Heijden and Verhagen (2002), which refers to the online retailers' handling of delivery, post-sales service, payment options, warranties and returns.

*Proposition 7: Online store settlement performance positively affects a consumer's attitude toward purchasing at an online store.*

### 3.8 Attitude Toward Online Store

Attitude is the overall evaluation of the desirability of a potential transaction with a specific online store.

Attitude has been proposed to influence behavioral intentions in multiple theories, such as the TPB (Ajzen, 1991) and the TRA (Fishbein and Ajzen, 1975). Applied to the online store consumer behavior context of this study, favorable attitude towards an online store is likely to encourage consumers to acquire information, to facilitate the act of providing information, and also to conduct monetary transactions with a given online retailer.

### 3.9 Intention to Purchase at Online Store

Intention to purchase at an online store is the user's likelihood to use an online store (Ajzen and Fishbein, 1980), maintain business relationships, and conduct business transactions. This is usually measured by consumers' willingness to buy and to return for additional purchases. Baker et. Al. (1994) found a link between store image and intention to purchase a product. Even if consumers finally decide not to purchase, it is important for marketers to know how to bring consumers to the online store, initiate communication, collect valuable feedback information, and encourage future transactions (Hoyer and MacInnis, 2001).

*Proposition 8: A consumer's attitude toward purchasing at an online store positively affects his/her intention to purchasing at an online store.*

### 3.10 Moderating Effect of Cultural Factors

Culture is a collective phenomenon. People learn patterns of thinking, feelings, and potential acting from living within a defined social environment, normally typified by country. Individual consumer tastes and purchasing patterns are thus partly determined by the collective values of their local community (Chau et al., 2002). If this notion is taken into the online store, different response may be generated toward a globally generic online store design.

Empirical research has found significant cultural difference across international user communities and are further supported by Hofstede's work. He concluded that research in one culture may not be generalizable to another.

According to Hofstede's cultural consequences theory (1980), there are five dimensions in a culture: power distance, uncertainty avoidance, individualism versus collectivism, and masculinity versus femininity, and long-term versus short-term orientation. A cultural dimension is relevant to attitude toward online store.

Individualism/collectivism refers to the basic level of behavior regulation. People high on individualism view self and immediate family as relatively more important than the collective. Collectivist societies focus on maintaining harmony by going along with the in-group's wishes and promoting long-term relationships (Bond and Smith, 1996). In general, once collectivist

societies establish a positive attitude toward something, they tend to internalize it and take it into their in-group circle. Thus, we would expect that a collectivist culture would influence its members to want to maintain harmonious relations with those vendors. Member of individualist cultures prefer self-sufficiency and should feel no mutual influence toward the maintenance of group harmony. Chau et al. (2002) suggested that Online testimonials and links to related chat groups could strengthen the social communications of the collectivist consumers who respect social relationships and their shared loyalty.

Short versus long-term orientation is people's basic reference time frame; short-term involves the tendency toward consumption and maintaining materialistic status, and long-term suggests thrift, perseverance, following tradition, and deferred satisfaction. According to Hofstede (2001), a culture of long-term orientation emphasizes persistence and thrift, in addition to respect for tradition and people feel free to put off making purchase at an online store until they are comfortable with it. Consumers of a long-term orientation society may also be less demanding of immediately online store satisfaction and have higher tolerance of errors or misdelivery if they can see a trend toward incremental quality improvement. For a short-term oriented consumer, the time concept is absolute and demand for temporal precision is high.

When masculinity is high, online store consumers may act more aggressively in their intentions and expression. This action may be more self-centered and less group-oriented.

The uncertainty avoidance describes the extent to which a society feels threatened by uncertain and unstructured situations and the eagerness to avoid such situations. This orientation may emphasize controls achieved in strong procedural and technically oriented online store navigation. A less structured online store or unfamiliar store name could prevent the consumers from using it.

Power distance is the degree to which the less powerful accept the prevailing distribution of power, and the extent of adherence to formal authority channels. High power distance cultures have members who are much more comfortable with centralized power than lower power distance cultures. For an online store, customers in a low power distance society would be less desirable to influence or control the services they received.

*Proposition 9: Online store image dimensions and their effect on attitude toward online store and purchasing intentions differ cross-culturally.*

## 4. SUMMARY AND RESEARCH IMPLICATIONS

One of the most basic concerns of online stores is

finding and retaining customers. Our work tapped on this question from the online store image determinants perspective and identified seven antecedents of online store image and their influence on the intention to purchase online. They are the perceived online store usefulness, perceived online store ease of use, online store enjoyment, online store style, online store familiarity, online store trustworthiness, and settlement performance. The most effective way for online retailers to develop profitable exchange relationship with online consumers is to earn their trust by have a trustworthy online store image. As more and more competitors are having similar online presence which convenience nearly costless switching for online shoppers, the enjoyment of an online store becomes an important consideration to sustain the interest of shoppers and earn their loyalty over other online stores.

The inclusion of the cultural dimension help augment the explanation of online store acceptance and usage by consumers across culture, which is very necessary as more and more online stores targeted at global customers.

Our findings can help online retailers predict consumer's willingness to accept and use their online stores, diagnose the reasons for low acceptance for existing stores, and develop corrective steps. The central point is consumer attitude towards using online stores. If consumers have more positive attitude, they are more likely to accept and use online stores. The model also provides insights on how to achieve this: a more positive consumer attitude can be achieved by improving an online store's image.

While the patterns of online consumer purchasing are gradually becoming standardized, localized online store addressing local consumer preferences are also increasing (Chau, 2002). Therefore, retailers should tailor the online store by taking cultural differences into consideration.

A number of limitations are inherent to this study. We will only study the influence of online store image and cultural factor moderation on intention of purchasing at an online store which is different from actual purchase. There are more factors needs to be explored as how the mental process of making a purchase decision made. In this study, we use cultural influence as a collective factor, future researches should explore the possible interactions between the dimensions of culture for more insightful conclusions.

## ABSTRACT

This research gives empirically grounded insights into e-business adoption in conjunction with factors usually considered in SWOT (Strengths, Weaknesses, Opportunities, and Threats) analysis in Austrian micro and small to medium sized software enterprises. The study evaluates the degree in which the Internet is used in supporting the firm's primary activities in marketing and sales based on primary data collected from 141 Austrian software firms. The results show that internet usage in this area is dependent on the size of the company. While almost all small to medium sized enterprises apply e-business to some degree, many micro enterprises do not seek to utilise possible potentials. The study reveals that firms perceiving their relative strengths on branding, pricing, product diversity, internationalisation, and access to new technologies have adopted more advanced e-business support. From the external perspective, organisations more intensively relying on e-business tend to experience less competitive pressure, have lower capital resources, and consider international markets more often as business opportunities than their competitors.

**Keywords:** software industry, e-business, e-marketing, SMEs, success factors

## 1. INTRODUCTION

Small businesses worldwide occupy an important economic position since they constitute key drivers of innovation, economic stabilisation, and employment [1-4]. This also seems to be the case for the Austrian computer software industry [5]. The software business itself is highly competitive, complex, knowledge-intensive, and characterised by a highly globalised as well as dynamic business environment. Software enterprises are therefore increasingly reliant on utilising new strategies to remain competitive. The Internet provides managers with opportunities to fortify and strengthen their competitive advantages [6, 7]. Recently published academic findings show a wide spectrum of possible effects of e-business on organisational performance [8]. The potential of e-business is believed to be a precondition for the success of future business organisations [6]. E-business is seen as a means to strengthen the competitiveness of firms [9]. Small software businesses tend to offer selective products and services connected with limited buying mobility of potential customers, instead of mass products where infinite multiplication of choices exist. It is believed that selective brands drive e-business as an strategic opportunity [10].

Empirical research that uncovers the impacts of e-business and relationships between utilisation rates and strengths, weaknesses, opportunities and threats (SWOTs) is underdeveloped. This paper answers the call for more exploratory, empirically grounded work [11] by focusing on: (i) e-business utilization, (ii) and interdependencies between SWOTs and e-business utilization. In all steps of analysis the focus lies on

micro as well as small to medium sized enterprises in the Austrian software sector. This article is restricted to Business to Consumer (B2C) e-business covering all offline and online marketing transactions using Internet based information and communication technologies. Marketing/sales is seen as the most frequently area impacted by e-business, i.e. it affects first ways in which the firm operates with the market [4]. The work assesses the impact of the Internet's growing influence on marketing strategy and possible relationships with perceived SWOTs. It does not elaborate on e-business models, frameworks, and adoption as well as operation practices.

The article is organised as follows. The chosen methodology and details concerning the acquisition of data are given in the next section. Thereafter, the frameworks for analysing the endogenous and exogenous situation are presented. This is followed by the analysis of the empirical data, which comprises the firm size distribution and e-business adoption in the industry as well as endogenous and exogenous perspectives. The last section concludes the article.

## 2. METHODOLOGY

The methodology employed is an empirical study of the Austrian computer software industry undertaken in the year 2000. The supplied address material for the study contained not only all Austrian software companies but also many hardware manufacturers and other IT firms. Therefore the empirical work undertaken had to consist of two steps. The first step allowed the screening of the provided address material in order to filter out the relevant software companies for the second main step of

analysis. In order to be included in the main sample, firms had to belong to the software industry, which was divided in three segments: Packaged software (SIC 7372, respectively NAICS 51121, 334611), custom software and software related services (SIC 7371, 7373 respectively NAICS 541511, 541512) [12]. Although custom software, i.e. software that is produced only once, is viewed as service output [13] this segment was considered separately. For both, the pre-liminary and the main analysis, the design of a questionnaire which was validated in several pre-tests was necessary. For the pre-liminary phase random sampling was employed and the 600 chosen companies were contacted by telephone. The achieved response rate was 70.4%. Some companies could not be contacted, because they had ceased to exist, the address was wrong or could not be found, etc. These neutral dropouts were considered in the calculation of the response rate and therefore did not decrease the return quota. On completion of the preliminary analysis structured face-to-face interviews followed in the main step of analysis, which based on a stratified and disproportional sample with subgroups according to company size. The rate of return for this second and main step of the study was 55.6%. After completing both, the pre-liminary and main step of analysis, non-response effects were examined. The analysis (regarding known distributions of variables of the Austrian computer software market such as the type of the organisation) revealed no significantly different characteristics between non-respondents and respondents.

The main questionnaire assessed general company information, the endogenous situation, exogenous data, and questions on co-operations. This endogenous section also covered the level of support of marketing objectives through use of Internet technology. The question was stated so that all organisations regardless of their software sub sector or their different e-business tactics were able to respond on their Internet utilisation rate. This included mentioning examples for online and offline e-business tools such as e-newsletters, web banners, web sites or portals. It is important to mention, that this article does not consider the area of e-procurement or e-sourcing. The assessed variable only refers to primary activities in marketing products and services.

### 3. SWOT ANALYSIS

Although there is an extensive amount of literature covering the strategic planning process, most approaches include a cyclic iteration of the following five elements. The strategic planning process begins with a statement of the corporate mission and goals (step 1). This is followed by the analysis of the organisation's external competitive environment (step 2) and the analysis of the organisation's internal operating environment (step 3). The internal analysis is followed by the selection (step 4) and the implementation of

strategies (step 5). The last step also involves the design of the organisational structure and control systems necessary to implement the chosen strategy [14, 15]. The focus of this article lies upon step 2 (external analysis) and 3 (internal analysis). The purpose of the external analysis is to identify opportunities and threats in the organisation's operating environment, while the internal analysis seeks to pinpoint the organisation's strengths and weaknesses. Many companies are conducting a SWOT analysis as part of the strategic planning process to identify the strengths, weaknesses, opportunities and threats before proceeding to the formulation of a strategy [16, 17]. SWOT analysis, respectively the analysis of "key" or "critical" success factors, belongs to the highest ranked set of techniques of strategic analysis used by firms in empirical surveys [18].

#### 3.1 Internal Analysis

This work seeks to analyse if the endogenous situation faced by the firm is interrelated with the applied level of e-business initiatives. For the development of the framework this research builds on the generic building blocks of competitive advantage together with a resources and capability based view: Efficiency, quality, customer responsiveness and innovation are the generic building blocks of competitive advantage that every software company can adopt. Achieving superiority requires an organisation to develop appropriate competence, which in turn is a product of the kind of resources and capabilities that a company possesses [15]. The variables that influence the long-term business success were therefore categorised into six areas:

- Resources
- Capabilities
- Efficiency
- Quality
- Customer responsiveness
- Innovation

The distinctive competence of a software company arises from two complementary sources: its resources and capabilities. The distinction between resources and capabilities is important in understanding what generates specific competence. Without the appropriate resources, the company may not be able to create a distinctive competency [15]. The inquired variables contributing to the resource-based view were "acquisition of venture capital", "equity capital situation", "trademark/label" and "image". Variables used to assess the capabilities of the organisation were "internationalisation capabilities", "order/project procurement", "organisational structure", "adherence to costs and schedules", "employee motivation" and "employee qualification". While only efficiency was not divided into sub-areas, quality was analysed by the factors "product quality" and "business process quality", customer responsiveness was represented by the variables "product diversity", "price levels", "customer

satisfaction", "level of specialisation" and "customer orientation", and to innovation the variables "know-how embedded in company" and "access to new technologies" were attributed. Although the inquired variables were allocated into different groups, they are highly interrelated. For example, factors contributing to innovation such as "know-how embedded in the company" or "access to new technologies" can also enhance quality, efficiency and customer responsiveness.

### 3.2 External Analysis

The independent variables of the external perspective were subdivided into potential exogenous growth barriers (threats) and potential exogenous growth drivers (opportunities). The selection of variables for both groups was influenced by the Porter's five forces model [19] and a wider macro-environmental view. Industries are embedded in a wider macro-environment, which comprises the technological, social and demographic, ecological, political and legal, and broader macro-economic environment [15, 20]. Changes in the macro-environment can have a direct impact on the five forces in Porter's model.

The potential exogenous growth barriers deemed as relevant for the analysis in conjunction with e-business were:

- Marketing/distribution in foreign countries
- Culture, varieties in language
- Trade/commerce law issues
- Governmental regulations
- Lack of ITC standards
- Acquisition of capital
- Labour legislation issues
- E-business maturity in Austria
- Austrian market size
- TC costs and infrastructure in Austria
- Software piracy
- Rivalry

As potential exogenous growth drivers the following criteria were selected:

- EU Software patent protection initiative
- Break-up of the former eastern bloc
- EU east expansion
- EU domestic market
- Liberalisation of telecommunications

## 4. EMPIRICAL RESULTS

### 4.1 Distribution of company size

The empirical data showed a strong overbalance of smaller software enterprises in Austria: Micro-enterprises (ME) account for 55.7% of the Austrian software organisations, 32.2% can be attributed to small-to-medium sized enterprises (SME), and 12.1% to large enterprises (LE). Classification was performed

using data on number of employees, turnover and independency following the definition proposed by the Commission of the European Community (EC, 1996). The applied criteria and the approximated overall number of software enterprises in Austria are presented in Table 1. In Austria the average firm size has declined in line with smaller firms entering the industry. Especially at the end of the 1980's and the early 1990's annual growth rates of over 20% (measured by number of enterprises in Austria) caused the decline of average firm size.

Table 1. Company size distribution

Size	Emplo yees	Turn over Mio.€	Indep end. <sup>1</sup>	No. of comp. (rel.)	No. of comp. (abs.)
ME	1-9	< 7	< 25%	55,7%	1.082
SME	10-249	< 40	< 25%	32,2%	625
LE	> 250	> 40		12,1%	235
Total				100%	1.941

<sup>1</sup> Capital share in external ownership

In the following sections analysis was performed only for the MEs and SMEs which constitute the research focus of this article. Consequently, from the 174 datasets 91 MEs (weighted N=97) and 50 SMEs (weighted N = 56) were included in the analysis, whereas two SMEs did not respond on e-Business utilisation.

### 4.2 E-Business Adoption

This study assessed the degree in which the Internet is used in supporting the firm's primary activities in the marketing area on an interval-scale from 1 (never) to 5 (very intensively). To test whether MEs and SMEs have identical distributions the Mann-Whitney U Test was applied, which is a nonparametric alternative to the independent-sample Student t test. It revealed that significant differences ( $p < 0.05$ ) exist. The data showed that in the mean SMEs are more intensively engaged in e-business compared with MEs. The following exploratory analysis was undertaken for each group of companies classified by their size separately.

The data set comprising only MEs exhibits a clear kurtosis and low skewness, i.e. indicating a very symmetric distribution. The variability of the data set is high. A great part of the organisations ignore e-business while approximately the same proportion of respondents already embraces e-business based transactions. Traditional marketing and communication channels are still predominant in the case of MEs. Many companies do not even build on the simplest e-based methods. Among SMEs, the distribution changes significantly. In SMEs, the utilisation rate of e-business is concentrated around a high level of utilisation. Only a small minority of SMEs have not implemented any e-business initiatives.

#### 4.3 Internal Analysis

The endogenous success factors given in a previous section had to be rated by managers of Austrian software companies on an interval scale based on our local school grading system from 1 (very positive) to 5 (very negative) as perceived in their own organisation. The first step of analysis was to test if there is a relationship between e-business utilisation and endogenous success factors. As a non-parametric test of statistical significance for bivariate analysis, the Chi square test was applied followed by an analysis of cross tabs with a special focus on standardised residuals to identify influential observations [21]. The strength of a possible relationship between success factors and the size of the company was analysed by calculating the Spearman rank correlation coefficient. Again, a non-parametric measure was used, which does not make any assumptions about the underlying frequency distributions.

The following analysis was applied in multiple steps. The first step comprised MEs and SMEs grouped together, followed by separate steps of analysis for each group of companies. Viewing both MEs and SMEs together, the study identified seven out of the twenty success factors analysed that showed differences in how they were rated by managers dependent on the rate of e-business adoption. Among MEs, six variables remained. Considering SMEs, four factors showed a significant relationship (see Table 2). It can be noted, that due to the impact of sample size on statistical power, less statistical significance is achieved with SMEs, where the number of observations is lower (50) compared to MEs (91). The endogenous situation improves with e-business utilisation for almost all identified relationships. The analysis of residuals for non-correlated factors has shown the same tendency.

The internationalisation capabilities improve, especially in SMEs, with higher e-business adoption levels. This reflects that the use of information and communication technologies in general, decreases the costs of distance, especially for more product rather than service oriented firms. The Internet is an enabling technology to reach new customers and suppliers in an affordable, more efficient and effective way [9] without the necessity to set up and maintain local branches in foreign markets. For MEs, the data shows that firms that see their relative strengths in the areas of trademarks/labels, product diversity, and price levels are more intensively engaged in e-business. These factors seem to be key strengths that motivate software firms to market their products and services in the Internet, consequently not fearing the associated global transparency. The ability to access new technologies is positively related with higher e-business adoption levels. Another study reported that the highest barrier for SMEs to doing business on the internet is the lack of technical skills [22]. This research adds empirical evidence to this statement applicable to

the software industry. The empirical evidence supporting this relationship is limited to the sample comprising all companies. The significance was lost when analysing both groups defined by company size separately. Efficiency was expected to be better in organisations with more e-business supported operations. A significant relationship was detected for all companies analysed together, but no sensible pattern underlying the relationship was identified. The same situation applies to product quality. A surprising indication is that MEs with lower customer orientation levels have more widely adopted e-business. The link between firms and their customers is believed to be strengthened by enabling e-business. Finally, the ability to acquire venture capital improves with the level of e-business diffusion. In general, MEs and SMEs with venture capital background passed a sales and marketing due diligence, which gives an explanation for their above average inclusion of state-of-the-art information and communication technology in their marketing models.

Table 2. Identified endogenous success factors showing dependencies by Chi<sup>2</sup>-Test and/or Spearman Rank Correlation Coefficients

No.	Variable	Classification
1	Internationalisation	Capabilities
2	Product diversity	Customer responsiveness
3	Price levels	Customer responsiveness
4	Customer orientation	Customer responsiveness
5	Efficiency	Efficiency
6	Access to new technologies	Innovation
7	Product quality	Quality
8	Trademark/label	Resources
9	Acquisition of venture capital	Resources

To identify how and if the significant endogenous criteria relate as sets to the e-business utilisation variable, two stepwise regression analyses were performed for each group defined by company size. It was therefore implicitly hypothesised that a multivariate model can be found, that significantly predicts e-business utilisation as the dependent criterion. The results of the stepwise analyses are reported in Table 3. For MEs, five steps were calculated, i.e. while five of six factors retain in the regression equation, the trademark/label factor was omitted. Due to the stepwise approach, all remaining factors significantly contribute to the model and therefore explain e-business utilisation. The extent of change in e-business utilisation for each 1-unit change of predictors seems to be similar. The direction of the change is different for product quality and customer orientation compared with the other factors significantly contributing to the final model. Product diversity was the first measure to be included in the stepwise calculation. Specifically, 31% of the

variance in e-business utilisation is explained by the five success factors in the final model ( $p < 0.01$ ).

Table 3. Results of stepwise regression analysis of e-business utilisation on significant endogenous factors in MEs

Step	Variable	B	R <sup>2</sup>	corr. R <sup>2</sup>	$\Delta r^2$
1	Product diversity**	-0.50	0.11	0.10	-
2	Product diversity**	-0.58	0.18	0.16	0.06
	Customer orientation**	0.56			
3	Product diversity**	-0.50	0.25	0.22	0.06
	Customer orientation**	0.65			
	Price levels**	-0.56			
4	Product diversity**	-0.46	0.31	0.28	0.06
	Customer orientation**	0.73			
	Price levels**	-0.55			
	Acquisition of venture capital**	-0.30			
5	Product diversity**	-0.50	0.35	0.31	0.03
	Customer orientation**	0.67			
	Price levels**	-0.57			
	Acquisition of venture capital**	-0.34			
	Product quality*	0.46			

\*  $p < 0.05$ , \*\*  $p < 0.01$

The regression constant was excluded from the table for every step.

For SMEs, four factors were included in the calculation, whereas two retained in the regression equation and together significantly explain e-business utilisation (see Table 4). With the final regression function, 16% of the variance in e-business utilisation is explained by the two variables ( $p < 0.01$ ).

Table 4. Results of stepwise regression analysis of e-business utilisation on significant endogenous factors in SMEs

Step	Variable	B	R <sup>2</sup>	corr. R <sup>2</sup>	$\Delta r^2$
1	Internationalisation*	-0.24	0.10	0.09	-
2	Internationalisation**	-0.28	0.19	0.16	0.07
	Trademark/label*	0.45			

\*  $p < 0.05$ , \*\*  $p < 0.01$

The regression constant was excluded from the table for every step.

#### 4.4 External Analysis

During the interview, the companies assessed the given exogenous variables according to their perceived influence on business growth on two different interval scales for each of the following groups: potential exogenous growth barriers and potential exogenous growth drivers. With these variables the same analysis as presented above was conducted. The analysis showed that observed e-business utilisation had a significantly

different distribution depending on a number of external factors more specifically in SMEs. An interesting indication is that managers in SMEs who are more intensively relying on e-business are experiencing less rivalry than their competitors. The marketing opportunity in the European Union is considered as a more important growth driver by software managers employed in firms with higher e-business utilisation. Finally, firms with lower capital resources more intensively exploit e-business. For the remaining factors, no clear direction of the dependencies was identified.

Table 5. Identified exogenous factors showing dependencies by Chi<sup>2</sup>-Test and Spearman Rank Correlation Coefficients

No.	Variable
1	EU domestic market
2	Labour legislation issues
3	Marketing/distribution in foreign countries
4	Acquisition of capital
5	Austrian Telecommunication costs and infrastructure
6	Rivalry
7	EU Software patent protection initiative

In analogy to the previous section, stepwise regression analyses were performed to complement the analysis with a multivariate method considering all detected significant variables together. Since no multivariate dependency profile was detected for MEs, the analysis was undertaken for SMEs only. The calculation process based on the identified exogenous factors as predictors was not able to conclude with a sensible and statistically significant model.

## 5. CONCLUSIONS

The paper provides empirically grounded insights into e-business utilisation in conjunction with related endogenous as well exogenous factors for MEs and SMEs in the Austrian software industry. In MEs, the usage of e-business tools in marketing their products and services is diverse with many organisations ignoring e-potentials. Among SMEs, e-business is variability is much less, i.e. most companies already seek to complement and enhance their marketing skills with e-business tools. They exploit e-business as an additional marketing channel, allowing for a global reach. They therefore follow Porter's argument that organisations should use the Internet in conjunction with their traditional business models and activities [7].

The analysis of the internal situation faced by the firm showed that a number of success factors were perceived as relative strengths in companies with better e-business support. E-business can be advantageous or disadvantageous to the business strategy of small firms [22]. Behind this background it does not seem surprising, that branding and pricing together with an attractive product portfolio were identified as key

strengths connected with the decision to engage the global market via the Internet. The ability to access new technologies seems to improve with higher levels of e-business adoption. If e-business is considered as a technology based innovation meant to redesign or complement primary activities in marketing and sales, it seems reasonable to expect that technology innovators among SMEs and MEs should show a higher e-business adoption rate. A surprising result was that customer orientation decreases with the level of e-business support in MEs. The external perspective embracing a number of factors regarded as threats and opportunities showed a less number of factors with significant relationships. Companies more intensively relying on e-business tend to experience less competitive pressure, have lower capital resources, and consider the international markets in the European Union as a more valuable business opportunity than their competitors.

In addition to correlation and dependency tests, multivariate regression analysis was applied to see if the variation of e-business utilisation can be explained by a multivariate consisting of the endogenous, respectively exogenous criteria for MEs and SMEs separately. The results showed that the multivariate relationships were found in the endogenous framework. Although exploratory regression models were calculated, this study can not help to distinguish between causes and consequences of e-business adoption.

Due to the highly globalised nature of the software industry, the findings should also be applicable for other countries, especially in the European Union. Future e-business research at our department will focus on in-depth case-based analysis to create an Austrian taxonomy of e-business strategies for small software business which can be compared with the wide selection of approaches, typologies as well as other taxonomies brought forward in academic literature.

## Extreme Availability: Determining the Limits of Availability in Commercial Systems

David W. Coleman, Todd W. Mummert

IBM T.J. Watson Research Center, Hawthorne, NY, 10532, USA  
{xinu, mummert}@us.ibm.com

### ABSTRACT

High availability has become increasingly important to businesses with the advent of the Web and various associated e-commerce services. This paper describes the key attributes of the very highest availability systems. Such systems and their associated support environments are qualitatively different than other systems, even other high availability systems; for the purposes of this paper these systems at the current limit of possible availability are termed *extreme availability* systems.

**Keywords:** High availability, fault tolerance, commercial systems

### 1. INTRODUCTION

The basic requirements that any trading floor application for the New York Stock Exchange (NYSE) needs to meet are fairly easy to define. The system needs to be extremely reliable, highly available, very fast, and highly scalable. While these requirements are not unusual *per se*, the levels needed by the NYSE are well beyond what most commercial off-the-shelf software provides. The NYSE is one example of an *extreme availability* environment, where no outage during trading hours is acceptable.

Historically, extreme availability has been a specialty area, of interest mostly for space-craft systems and those systems where failure would cause significant destruction and loss of life. The usual techniques for improving availability, such as redundancy and independent backup systems, have been used with great success in such systems.

Commercial systems are extremely cost sensitive, although the degree of sensitivity varies by industry. Most businesses think about availability in much the same way that they think of disaster recovery costs – they determine the cost per hour (or sometimes per minute) of an outage, and then take appropriate steps to mitigate outages using the outage cost per hour as a cap on potential mitigation expenses. One corollary of this approach is that when business critical systems are computerized the willingness to spend to increase availability goes up sharply, since the expense cap becomes tied to the entire business revenue stream.

Given this background, it should come as no surprise that e-commerce is causing many companies to become much more concerned about high availability, and in some cases businesses are starting to look seriously at what is required to achieve extreme availability. At the moment, financial companies are most interested in extreme availability, partly because they are often the most advanced in computerizing their business

processes and partly because they tend to have the highest cost per hour for outages. It appears, however, that a secondary effect of the shift to e-commerce is that high availability is becoming a critical competitive attribute –and that extreme availability may in turn start becoming a competitive differentiator.

There are a few key ideas which appear over and over when considering the various aspects of availability. They are listed here both as an introduction to the concepts and as a convenient reference point.

**MTBF** stands for mean time before failure, or sometimes mean time between failures. These two phrases are equivalent only for those cases where the curve which describes the failure probability over time is a negative exponential curve, but as it happens such a curve is frequently a good fit for hardware failures, particularly for electronic or electrical equipment. In summary, MTBF is a measure of how long something is likely to stay up. Generally MTBF values are specified as some number of months or years.

**MTTR** stands for mean time to repair. It is a measure of how long it takes to fix something once it breaks. Note that the repair time includes whatever time it takes to diagnose the problem, acquire the repair components, pull the failing component, do whatever repair is needed, and reinstall the now working component.

**SPOF** stands for single point of failure. A single point of failure is a system or environmental component which, when it fails, takes down the entire system. The significance of a SPOF is that the reliability of that component will be an upper bound on the overall reliability of the system. In general, any SPOF is a weak link in a high availability chain.

This paper provides a background in the general approaches and concerns for very high availability systems. While these general approaches are well known in certain areas, it is useful to revisit them in the

context of distributed e-commerce systems to understand what aspects are most important in that environment. To do this, the paper follows the general overview with an overview of the techniques and approaches used by those organizations which are most aggressively pursuing extreme availability. Finally, some general information is given from case studies of such extreme availability systems, to indicate what the limits of the commercial state of the art are today.

## 2. FAULT TOLERANCE

Fault tolerance is the study of how to design systems or subsystems so that they continue to operate correctly in the presence of components which fail. Normally the measure for a successful design is an increase in the overall system MTBF. There are some curious tidbits from this area of study, such as the fact that redundancy can actually *decrease* system MTBF. To understand how and why such things can happen, it is necessary to understand how component MTBF can impact system MTBF. [1] [2]

### 2.1 MTBF –Underlying Assumptions

Large systems are composed of many parts, and to compute the MTBF for such large systems we need a way of composing the MTBFs for the parts. In general,

$$\begin{aligned} &P(\text{exactly one of } E_1 \text{ and } E_2 \text{ occurs}) \\ &= P(E_1) + P(E_2) - (P(E_1) * P(E_2)) \end{aligned} \quad (1)$$

Note that for sufficiently small probabilities, the product term will be quite small with respect to the overall value, and hence we can approximate the probability that exactly one of  $E_1$  and  $E_2$  occurs with the sum of the probabilities of  $E_1$  and  $E_2$ . (Since for fault tolerance we are dealing with failure probabilities, and most failure probabilities for IT systems are less than 5%, this simplification is useful and fairly accurate. Note that  $5\% * 5\%$  is 0.25%, while the sum is 10%, and that further the accuracy of the approximation improves as the probabilities get smaller.)

Because we are interested in the expected life span (Mean Time Before Failure), rather than the probability of failure in a given time span, we must find a new function of  $P(E)$  which yields this information. For random probability distributions this can be quite difficult, but it turns out that a useful approximation is to assume that the probability is memory-less, which means that the probability of failing in the next time interval is independent of how long it has already been in service. With that assumption, we get

$$MTBF(E) = 1/P(E) \quad (2)$$

It turns out that many IT devices actually exhibit a bathtub curve probability, with a high infant mortality rate and a high wear out rate joined by a long period of essentially constant and low mortality. Manufacturers

can convert such devices into memory-less devices by using a burn-in period to eliminate infant mortality, and setting the nominal end of life (or end of warranty) prior to the rise due to end of life mortality.

For a device with a 5% probability of failure in any given month, we will therefore get a 20 month MTBF. Most systems are composed of many modules. If the modules fail independently, we can compute the probability of the system failing. In general, for any set of  $N$  identical parts the MTBF for the entire set is  $1/N$  times the MTBF for one such part.

### 2.2 Failure Modes

Since we are interested in fault tolerance, it is natural to ask about the failure modes of the various devices we are considering. Unfortunately, this question is extremely hard to answer with complete accuracy for most devices. Further, the answer to such a question is tightly tied to the exact technologies used, so even having the answer for a given device doesn't necessarily help in determining the answer for another similar but not identical device.

There are a few general principles which can help increase fault tolerance. The first such principle deals with what are commonly called soft, or transitory errors. Soft errors have the property that the probability of occurrence is independent of the work being done, and further they do not always occur even when the same work is done. There can be various causes for soft errors, but in terms of fault tolerance the ultimate goal with soft errors is always the same – to mask the occurrence of the error in such a way that there is no immediate fault generated. The solution in these cases always comes down to redundancy, and typically it is implemented via error correcting codes. While ECC is a large and complex field of study, it is also sufficiently well understood that such codes are in widespread use by device manufacturers to control transitory errors. Such codes are used in all disk drives, and on almost all communication channels.

Workload independent hard errors (also known as non-transitory or permanent) can also be handled by manufacturers by using redundancy, but in this case the redundancy needed is additional hardware.

Unfortunately there are several additional classes of errors which do not easily lend themselves to general solutions. Workload dependent errors, such as the floating point problem in Intel processors, are one major example. Additionally, many devices have partial failure modes, where things are neither working completely nor failed completely. While most manufacturers attempt to identify such problems with testing, even the most rigorous testing will occasionally miss such problems.

There is one final general approach to dealing with failure which can be helpful, both in the real world and for theoretical analysis of fault tolerance. This approach is called failstop, and it works by forcing all faults into the same terminal state, namely the stopped state. This approach significantly aids in the design and operation of fault tolerant systems, and as will be seen below it also aids in the analysis of the behavior of such systems.

### 2.3 Fault Tolerance Approaches

In general, fault tolerance requires two things, namely a way of detecting failure and enough redundancy to allow the failure to be overcome.

Under certain conditions, it is possible to turn any device into a failstop device. The simplest way to do that with non-failstop components is to duplicate the device, and then use some kind of comparator to see if the outputs of the two copies of the device agree. If the outputs agree, the device continues to work. If the outputs disagree, the device stops. For this process to be feasible, of course, it must be possible to build the needed output comparator. The major drawback to this simple form of failstop creation is the impact on MTBF. Because there are two copies of the basic device, the failstop device has an MTBF which is no more than  $\frac{1}{2}$  the MTBF of the original device. This can of course be mitigated by using more copies of the device; with three copies (and a more sophisticated comparator) the failstop device has an MTBF of  $\frac{5}{6}$  of the MTBF of the original device. (An additional advantage of triplex or higher redundancy arises if soft errors predominate in the failure modes for the base components. In that case the comparison process will completely eliminate the soft errors, and significantly boost the overall MTBF.)

Although building failstop devices doesn't sound obviously attractive at this point, things become better once higher layers are built on top of such failstop devices. With non-failstop components, the device must necessarily fail as soon as there is no longer a majority of devices working. With failstop components, the device can continue to work as long as at least one of the components is working, since each component will either work correctly or stop. While this won't ease the redundancy cost of the additional hardware, it has a substantial impact on MTBF. With a duplex device, the overall MTBF moves from  $\frac{1}{2}$  the component MTBF to 1.5 times the component MTBF. With a triplex device, the overall MTBF moves from  $\frac{5}{6}$  the component MTBF to  $\frac{11}{6}$  times the component MTBF.

The most interesting advantage of building with failstop components only appears with one additional assumption. If it is possible to replace failed components without taking down the entire device, and

synchronize the new component if necessary, then the MTBF calculations change significantly. The device will fail if all but one of the components are unavailable, and then the remaining component fails. This yields the following equation for a device made with  $n$  copies of a failstop component:

The MTBF for the  $n$  component device with repair is:

$$\text{MTBF}/n * (\text{MTBF}/\text{MTTR})^{n-1} \quad (3)$$

or rewriting slightly

$$\text{MTBF}^n / (n * (\text{MTTR})^{n-1}) \quad (4)$$

Using our usual 95% reliable components, and assuming that repair takes a full day, we find that the MTBF for a duplex device is made from 20 month MTBF components is approximately 1000 months, or roughly 80 years. Using the same components, a triplex device will provide an MTBF of approximately 80,000 months, or roughly 6500 years.

Note that using a comparator and duplex or triplex (or more) is not the only way to provide fault tolerance. The key to fault tolerance is spare hardware and some way to detect failure, with the spare hardware used to correct the detected fault. As an example of another alternative approach, consider RAID 5 disk drives. What is done for RAID 5 is to use a redundant coding on the, with the extra drives needed by RAID 5 used to increase storage to hold the extra bits required by the redundant encoding. [3] [4] [5]

### 2.4 The Bad News

From the preceding discussion, it is clear that whenever we have workload independent failure modes, either soft or hard, and devices which are memory-less in their failure mode, which are relatively reliable and easy to repair, it is possible to build fault tolerant devices with very high MTBF.

An obvious question is then what large system components do not exhibit the needed properties. And unfortunately there is one key area which does not fit the picture—software. Even worse, the characteristic which is least compatible with the assumptions is the primary assumption behind much of the fault tolerance work, namely the assumption that most failure modes are workload independent.

When most of the failures are a function of the workload done, no voting scheme which uses multiple copies of the same software increases reliability.

As a practical matter, most people designing systems for high availability deal with the issue of software faults by relying on one of the demonstrated advantages of software, namely that the defect rate decreases with use. Thus, it is common for systems with high sensitivity to failure to prefer software which has been in wide or long term use elsewhere to take advantage of the

improved defect rate. Additionally, there is likely to be a much greater emphasis on testing for such systems.

One additional area of workload dependent failure warrants special attention currently. This is the area of security issues and faults. While there have been security issues and bugs since the earliest days of computing, even in systems which were designed from the ground up with security in mind, the Internet has increased the significance of such issues. The problem is that the Internet makes networked computers more widely available. While this is a good thing in terms of increasing the usefulness of such computer systems, it also allows those with harmful intentions access to the systems. These people will typically search out security faults of various types, in order to exploit the weaknesses for their own purposes.

### 2.5 Fault Tolerance Summary

Standard failure analysis has yielded tremendous gains in hardware component reliability (disk drives have gone from MTBF of hundreds of hours to MTBF of tens of thousands of hours over the last few decades for instance). Further, the work on high availability systems has yielded a number of highly effective techniques for composing the improved components into larger systems which are even more reliable (one notable innovation being RAID 5).

The approaches used for hardware fault tolerance have not been noticeably successful in providing software fault tolerance. Curiously enough, until recently this has not been a major issue in the design of highly available systems, largely because the software failure rate was sufficiently low that other modes of failure dominated in the overall failure modes. Improvements in hardware reliability, coupled with a trend toward attacks on systems via software defects, are likely to increase the urgency for solutions in this area going forward.

## 3. HIGH AVAILABILITY

High availability is yet another way of looking at the issue of IT system faults and the key ideas of MTBF and MTTR. In the case of high availability, the focus is on the end user experience. Thus, high availability is normally expressed in terms of per cent availability of the process or function supplied by the associated IT system. Note that availability will be increased by either increasing MTBF or by reducing MTTR

### 3.1 Availability and Target Percentages

While availability is normally expressed in percentage terms, since those percentages are frequently over 90%, it can be useful to convert the percentages into minutes of downtime per year. Thus 99.9% availability is about an hour a year of downtime, while 99.999%

availability is about 5 minutes a year of downtime.

While this is easy enough to understand, there is a complication in how availability can be calculated which can impact the downtime numbers above. In computing downtime, some people exclude planned downtime (for things like upgrades or hardware maintenance), and some don't.

The mathematical calculations above are interesting. More interesting is the question of what end users should really expect. In general this is a hard question, which depends on many details of the actual system under consideration, but the following quote seems pertinent.

*The availability specification for the Windows NT server is about 99.5 percent. UNIX has something like 99.7 percent availability and OS/390 has 99.999. When you think about it, that means your unplanned downtime on an NT server will average about 50 hours per year. With UNIX, the number is around 26 hours per year. And, with OS/390, you are looking at 5 minutes of unplanned downtime per year. Considering the cost to companies for an hour of unplanned downtime -- \$100,000 for a retail operation, \$6 million or more for a brokerage -- you can see that the drive to client/server is a costly one. [6]*

### 3.2 Improving Availability

Improving availability is not an all or nothing process. It is possible to improve the availability of individual subsystems. This is fortunate, since the cost of applying high availability principles to entire IT systems will increase the cost of the system by a factor of 2 to 4, depending on system details.

The obvious place to start in improving availability is wherever outages are causing the most pain. For each such pain point, alternatives can be developed using the various techniques which have been outlined above. Then the cost of implementing the various alternatives can be determined, and weighed against the business benefit to be gained. As an example, let us assume disk drive failures are causing a significant productivity loss. A few alternatives to increase availability are backups (which can significantly reduce MTTR), raid arrays, various kinds of networked storage (SAN or NAS), and of course using a more reliable brand of disk drive. The disk drive business has grown sufficiently competitive that all the major vendors offer roughly equivalent MTBF ratings, so that alternative is unlikely to bring useful gains in reliability. Backups are likely the cheapest alternative, so if an hours long outage for restoration (and possible loss of any work done since the last backup) is acceptable, this might be a worthwhile alternative. Raid arrays will entail the cost of a new raid controller and additional disk drives for the particular raid mode chosen, but will provide

significantly increased MTBF, and in some cases lower MTTR also. Networked storage will entail acquiring the appropriate storage boxes, as well as some increased administrative overhead. Note further that both networked storage solutions and backup solutions can be shared among multiple systems, so even determining the cost of an alternative is specific to the business making the choice. Given the multitude of technically feasible solutions, business requirements and tradeoffs dominate in determining the exact nature and level of high availability appropriate for any given IT system.

Any business with a large number of similar systems can usually determine fairly easily which components most commonly cause outages. For smaller businesses, or for unusual configurations, it will be necessary to rely on outside data to determine the components most likely to cause problems.

One final point may be useful for any business working on improving availability. Initially it is easy to look at overall statistics on business wide outages and determine which areas need attention. However, once availability improves enough, even a large business is likely to find that the weekly variation in outage causes starts to disguise the underlying trends, and make it hard to gain further improvement. The exact point at which this occurs is largely a function of the size of the business, but in general this sort of problem will start to appear around 99.5% availability. When this starts to happen, it will likely be useful to shift to considering not overall outage statistics, but rather statistics on the longest outages. Normally at this point reducing the length of the longest outages will provide a significant boost to overall availability. [7]

### 3.3 An Overview of System Failures

As we have seen above, having information on what kinds of system or component failures to expect makes the process of improving availability much easier. This makes published data summarizing all failures, by source of failure, for a large number of systems of considerable value. There are, however, two problems with such data.

The first problem is that there are almost no such studies. The only published work we are aware of that cover all system failures for a large number of systems is the work covering an analysis done by the Japanese Information Processing Development Corporation (JIPDEC) in the mid 1980's. This study surveyed the outages reported by 1,383 businesses in 1985, and covers 7,517 outages with an average outage duration of about 90 minutes. This yields an overall MTBF for the systems of about ten weeks, and an availability of 99.91%. [8]

The second problem is that the data is very dependent on the technologies used in creating the system. While

there are specialists who can determine the expected reliability of a system, using detailed calculations on all the various components of the system, this work is quite hard and expensive – normally it is easier to simply observe actual performance. This is particularly true since one of the key components of the system, the software (operating system, middleware, and application) typically does not come with a rigorous MTBF guarantee.

Despite these two caveats, it is interesting to see what has been found, and combine it with the technology trends in the intervening years to provide some guidance on what areas will most likely benefit from improved availability efforts.

In the mid-1980's conventional wisdom was that disks were the major concern for reliability, because they were mechanical. This was borne out by disk MTBF values of about 10,000 hours, although some vendors were producing disks which were both significantly more expensive and more reliable. Although disks have remained mechanical, they now exhibit advertised MTBF values of 50,000 hours, and actual experience indicates MTBF values of between 5 and 10 years. While not all the MTBF news is good, as will be seen in the next section, in general computer hardware has become significantly more reliable, and requires significantly less maintenance than was true during the JIPDEC study.

But is improved hardware and maintenance enough? Note that while the MTBF with 1980's hardware and software was 10 weeks, even with perfect vendor hardware and software the JIPDEC average MTBF would only rise to 4 months. With an average repair time of 90 minutes, this would correspond to an availability of only about 99.95%. Vendor product improvements are clearly important, but also clearly not enough to achieve the high availability goals.

### 3.4 External Factors

It is useful to consider the impact of WAN connectivity and the power network, which are typically not under the direct control of the business attempting to provide a high availability system. In North America, communication line suppliers will provide service guarantees of 95% error free seconds, bit error rates of no more than 1 error per million bits, and 99.7% availability. Redundant message encoding and duplexing transmissions via independent paths can mask most transient failures, but 99.7% availability is significantly lower than even a PC server. Further, a 1998 study by RTO West, a Canadian power supplier indicated that for their system power was available at the point of delivery only about 98% of the time. Once again, this sort of low external availability can be overcome with careful system design.

### 3.5 Fault Tolerance Summary

There are five normal sources of outage: 1) Hardware; 2) Software; 3) Operations; 4) Maintenance; and 5) Environment. (Environment includes all items which are not considered part of the system of interest, such as the building(s) the system sits in or the power or machine room cooling systems.)

The base reliability of computer and network hardware has been improving for some time. One recent study suggests that even with PCs, which are normally considered the least reliable server alternative, it is possible to achieve 99.5% availability and an MTBF of about 35,000 hours. While this may change with increasing heat stress in newer PCs, it is still a very promising starting point.

On the other hand, there is no evidence that software reliability is improving anywhere near as fast. Further, virus attacks, which rely on defective software for their effects, seem to be increasing at a rather startling rate. This suggests that for the foreseeable future the limiting factor for availability is likely to be the software.

Operations and Maintenance outages are typically the result of human error and/or vendor design problems in tools or procedures.

Environmental outages include all the sorts of issues that are considered as part of a disaster recovery plan. It is clear from looking at just a few of these items that if they are not taken into account then environmental issues will provide an upper bound on availability significantly below 99%. On the other hand, with careful planning most or all such outages can be controlled.

It is worth noting that high availability is not an all or nothing attribute. By addressing any of the normal sources of system failure, the overall availability will improve. Similarly, by improving the MTTR for any source of failure, availability will improve. For most businesses, the key to improving availability is gathering the data which will cost justify the needed system changes.

## 4. EXTREME AVAILABILITY

Extreme availability is the ultimate form of high availability, when the desired goal is no outages at all, because the perceived harm to the business is immeasurably large. How does this differ from high availability? To answer that, a comparison is useful. In the United States, both the nuclear power industry and nuclear powered naval vessels were expertly designed with careful attention paid to fault tolerance. Further, in both instances the systems are run by thoroughly trained experts. Nonetheless, the nuclear power industry has had several "incidents", while no

such incidents have been encountered in the nuclear navy.

### 4.1 Critical Components

In even the most carefully designed fault tolerant system, there will be unexpected events. While such events will be rare with careful planning, proper handling is vital if outages are completely unacceptable.

In addition to the importance of people, most extreme availability organizations pay close attention to a number of other areas in order to achieve their results. These areas include culture, fault tolerance, upgrade procedures, testing, security, using mature software, documentation, and simplicity – each of which is covered in more detail in the following paragraphs.

The first common feature of extreme availability businesses is that they have a strong culture of reliability, which emphasizes such things as always taking extra care and always being ready for a surprise. While culture is always somewhat specific to the organization if appears in, extreme availability cultures seem to share certain traits.

As we have seen in earlier sections, there are a great many possible sources of problems. Extreme availability requires a fanatical attention to possible single points of failure. In power, for example, the building should have two power feeds, coming in on opposite sides of the building, from separate power substations. Each power feed should feed an independent electrical distribution network inside the building. The outside power should be backed up by batteries, which in turn are backed up by generators, with an on site fuel storage sufficient to last many days. Good planning might even get multiple fuel delivery contracts (with independent providers) which would start a week or so before the fuel store would be emptied.

One area where extreme availability organizations pay particular attention to fault tolerance is in the upgrade process for hardware and/or software. For upgrades, extreme availability organizations use a gradual rollout process of some sort, which allows the organization to observe the upgrade in actual operation. Further, this gradual rollout is coupled with a way to back out the upgrade if problems occur. Note that being able to do gradual rollout and immediate back-out (if necessary) may well impose additional requirements on the design for system redundancy.

Redundancy and fault tolerance can protect against random errors, but they provide no protection against systemic errors, such as a programming mistake or misconfigured hardware. The only remedy for such systemic problems is testing. Extreme availability organizations take testing very seriously. Testing

periods are never shortened. Frequently there are multiple independent testing organizations, and each of them has the ability to stop deployment. Testing is normally not under development.

In addition to systemic threats, there are the active threats from people who for whatever reason want to impact the system. Security precautions will include both physical security (site, building and machine room) and network security. When possible, the system should be isolated from the Internet. If Internet access is a key feature of the system, then layered protection against penetration attacks are needed, as well as a mechanism for handling denial of service attacks.

Security precautions are important, of course, but beyond that extreme availability organizations typically implement a higher than normal degree of isolation. For example, development networks may be fully independent of production networks. And of course testing environments are fully independent of both development and production.

Software is markedly different from hardware in the shape of its failure curve over time. New software is markedly more likely to fail than software which has been used by many organizations over several years. Many organizations recognize this effect by avoiding all x.0 releases. Extreme availability organizations extend that rule to try and avoid any commercial software until it has a track record with other organizations.

As we have seen from earlier sections, high availability relies on fault tolerance plus repair. Good monitoring is key to understanding when there is an otherwise transparent failure, and hence when repair is needed. A correct view of what is happening in the system also lowers the likelihood of an erroneous action being taken by an operator.

Extreme availability requires an unusually complete set of operational documentation. Why? People can be single points of failure also. Worse, even if you have several people cross trained you may find that the backup is out sick while the primary is on vacation.

Simplicity is a watchword for most extreme availability organizations. Simplicity means using the fewest pieces possible for the function needed, because of the impact on MTBF of additional components. It also means using simple administrative interfaces, to lessen the chance of error in an emergency.

#### **4.2 Extreme Availability Summary**

Extreme availability takes a high availability system as a base, and adds operations personnel with good skills handling emergencies and a strong culture of failure avoidance.

While this may sound simple, it is not. Any culture change is difficult, and the culture of high availability is not common in the industry. This means that it is a difficult adjustment for many.

### **5. CONTINUOUS AVAILABILITY**

As the Internet becomes more significant to business, increasing numbers of firms are looking at the issue of making some or all their systems always available. eBay, for example, attempts to make their systems always available. For convenience, this type of availability is called continuous availability. Given the success of the various approaches above in increasing availability, an obvious question is what impact the additional constraint of continuous availability might have.

At first blush, it would seem that there should be very little impact produced by the continuous constraint. After all, the most highly available systems are already up almost all the time. But in fact there is a substantial impact, and the reason is contained in one of the points touched on earlier, namely the variations in the definition of availability. Most very high availability systems have availability defined in terms of scheduled uptime. Or to put it another way, they do not include scheduled downtime in their availability calculations.

#### **5.1 Implications of No Scheduled Downtime**

As we saw in the section on fault tolerance, to get the highest levels of availability, it must be possible to repair a system while the system continues to operate. Given this, it seems it should be possible to achieve the same levels of availability for continuously available systems as for those that have some small degree of scheduled downtime.

The reason this is not in fact the case is that manual repair time is actually quite dangerous from a system availability point of view. The data in this area is quite hard to come by, and is also very fragmentary, but it appears that outages are approximately 30 times more likely during a repair session. This is of course a function of human fallibility. What appears to be happening is that, since repairs are a rare event, people are much more likely to make mistakes at that time than at other times. With scheduled downtime, such mistakes can be caught and fixed without impacting availability.

There is of course a considerable body of data on human errors during emergencies. (A continuous availability outage is naturally an emergency.) It is interesting to speculate on whether well designed repair procedures, which are protected against human error, could in fact allow continuous availability to be a trivial byproduct of high availability. Current hardware and software upgrade and repair procedures do not allow this. As a

result, companies such as eBay, which aim for continuous availability, have an availability target of 99.9%, while firms which aim for extreme availability are likely to have a target of 99.999%.

### 5.2 Continuous Versus Extreme Availability

Despite the fact that continuous extreme availability appears to be beyond the current state of the art, continuous availability and extreme availability still share a number of similarities.

Both continuous availability and extreme availability take as their base careful attention to high availability principles. Further, both rely on skilled operations personnel working in a culture which emphasizes availability.

The same cultural focus items which are important to extreme availability tend to be important for continuous availability, although there are a few differences which will be detailed below.

While continuously available environments need the same degree of fault tolerance as extreme availability environments, there is an additional requirement. The additional requirement is that repairs must be possible to a running system. This is a design constraint on the system, and it applies to all parts of the system. Notice for example that this can imply a need to be able to replace a power outlet without impacting any other outlet on the same circuit.

Gradual rollouts are important for both extreme availability and continuous availability, but for continuous availability the rollout process (or rollback process) must occur while the system is live. Once again this is a design constraint, but in this case the design constraint may impact such things as the software communication protocols, since a gradual rollout will create situations that could otherwise be avoided.

Security needs are similar in extreme availability and continuous availability, but for continuous availability it will be necessary to have security upgrades rolled out on a live system.

Monitoring is somewhat more complex for continuously available systems, since monitoring will be needed for the repair process also.

### 5.3 Continuous Availability Summary

At the moment, the very highest levels of availability appear to be unachievable in a continuous availability setting. Careful attention to the high availability precepts, combined with an attentive workforce, can achieve about 99.9% availability, or roughly 9 hours of outage per year.

## 6. CONCLUSION

While great strides have been made in improving IT hardware availability and in understanding the design principles and operating procedures which will aid in increasing availability, it remains true that high availability is neither easy nor free.

Well designed redundant hardware operated by skilled practitioners can achieve availability rates of 99.999% for key periods each day, or 99.9% on a continuous basis. Organizations which achieve such values spend significantly more on their IT infrastructure than the average commercial enterprise. Unfortunately as we move towards greater degrees of electronic integration between businesses, there will be a need to both close the gap in continuous availability and a need to make extreme availability feasible for businesses that do not have a large team of highly skilled operators.

## ABSTRACT

This is a research in progress paper discussing Internet banking issues both from the bank's point of view and from the customers' points of view. Based on literature it includes several factors that impact Internet banking. It includes several hypothesis derived from literature to be tested empirically. The research will be guided by the conceptual model presented as figure 2 in this paper highlighting the relationship between Internet banking and customer satisfaction and loyalty.

**Keywords:** Internet banking, customer satisfaction, customer loyalty

## 1. INTRODUCTION

Internet banking is one form of e-commerce that has gained a wider acceptance than others. In Australia all banks are now offering internet banking facilities to all its customers. As suggested by Chang [10] the evolution of information technology has significantly influenced the banking industry. Particularly, the advent of the Internet and the popularity of personal computers have created both an opportunity and a challenge for this industry. In only a decade Internet Banking has rapidly grown [2]. In 2001, the Market Intelligence Strategy Centre (MISC) reported that approximately 2.8 million people have used Internet Banking in Australia [50]. These figures increase rapidly with each new survey. A study from Taylor Nelson Sofre in 2002 revealed that 23% of Australians used Internet Banking and the Internet Banking adoption rate in Australia is greater than in the US and Britain [3]. In mid-2002, the MISC reported that 5 million Australians had used Internet Banking services [39]. Recent survey undertaken by the MISC shows that the number of Australians using Internet Bank had reached 7.7 million in September 2003, with an annual growth rate of 113% [33].

The rapid growth of Internet banking in recent years is a clear indication of consumer acceptance of this media. However, the impact of Internet Banking on customer satisfaction and loyalty in Australia is yet to be established as few studies have addressed this issue. In this paper we present a review of literature on internet banking and the factors that may impact internet banking and customer satisfaction and loyalty.

## 2. DEFINITION OF INTERNET BANKING

Internet Banking is defined as the usage of Internet and telecommunication networks to deliver banking services to customers [12, 14, 43]. Customers can inquire information and carry out most banking services such as account balance inquiry, inter-account transfers, and bill-payment via the Internet. There are different

perceptions of Internet Banking between the literature and practitioners. With reference to most Australian banks' websites, the term 'Internet banking' has been construed as the transactions relating to current and credit card accounts such as viewing balances, paying bills, and transferring funds. In contrast, in the literature, Internet banking includes the services relating to financing, insurance, investment, and new banking services [14, 43]. The latter will be referenced in this paper.

## 3. INTERNET BANKING TECHNOLOGY

According to Leong, Srikanthan & Hura [27] Internet banking is a web application based on client/server architecture in which Internet technology plays an important role. A basic architecture is illustrated in figure 1.

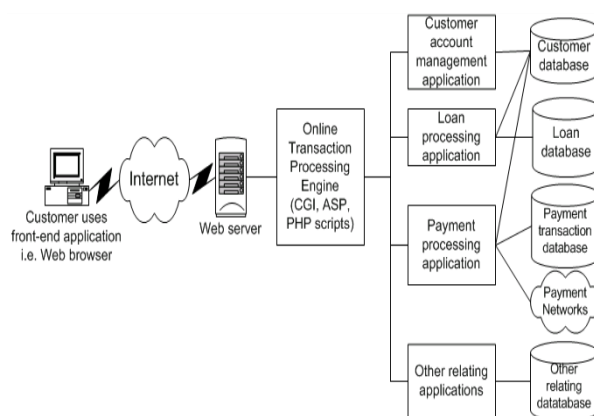

Figure 1: Internet Banking application architecture - adopted from Leong, Srikanthan & Hura (1998) and Turban et al. (2000)

Similar to all Internet transmission of information, with Internet banking security is an important concern for banks and customers [43]. All banks offering Internet Banking have taken special care to ensure security, privacy and confidentiality of information to all its customers. Basic security requirements to conduct business over the Internet are discussed below. *Authentication* involves the ability of an individual, organisation, or computer to prove its identity. Security systems accomplish authentication by verifying information that the user provides against what the system already knows about the user. *Authorisation* involves the control of access to particular information once identity has been verified. Authorisation is meant to limit the actions or operations that authenticated parties are able to perform in a networked environment. *Audits* include information on access of particular resources using particular privileges or performing certain security actions. It identifies the person or program that performed the actions. *Confidentiality* involves the secrecy of data and/or information, and the protection of such information from unauthorised access. For e-businesses confidentiality is of utmost importance in the protection of an organisation or company's financial data, product development information, organisation structures and various other types of information. Time related information such as a price list or confidential report can be crucial and need to be kept confidential until a certain time. Policies regarding the release of information must be included in confidentiality, as well as authorisation services. Confidentiality policy must ensure that information cannot be read, copied, modified, or disclosed without proper authorisation and that communication over networks cannot be intercepted. *Integrity* is the protection of data from modification either while in transit or in storage. E-commerce and e-business systems must have the capability of ensuring that data transmissions over networks arrive at their destinations in exactly the same form as they were sent. Integrity services must protect data against modifications, additions, deletions, and reordering parts of the data. Information can be erased or become inaccessible, resulting in loss of *availability*. This means that those who are authorized to get information did not get what they needed. Availability of information is an important attribute in service-oriented businesses that depend on information (e.g. airline schedules). When a user cannot get access to the network or specific services provided on the network, they experience a *denial of service*. *Nonrepudiation* involves protection against a party involved in a transaction or communication activity that later falsely denies that the transaction or activity occurred. Nonrepudiation services must be able to demonstrate to a third party proof of origin, delivery, submission and transport of the data in question [56].

Security protection includes physical security devices i.e. secure server rooms, unauthorised intrusion detector, organisation's security policies and related Internet security technologies. Authentication, digital

certificates, firewalls, Secure Socket Layer (SSL), Secure HTTP (S-HTTP), Secure Electronic Transaction (SET), Joint Electronic Payment Initiative (JEPI), and Open Financial Exchange (OFX) are important technologies supporting Internet Banking security [25]. SSL and S-HTTP are popular protocols for secure communications over the Internet at network level security and application level security respectively, using public key cryptography and symmetric key encryptions. On the other hand, SET is a standard/protocol for securing real-time credit card transactions over the Internet. This protocol enables E-Commerce applications to communicate between the customers, SET-compliant merchants and authorised third-party payment gateways.

JEPI and OFX are secure communication protocols. JEPI is known to standardise payment negotiations by assisting consumers and merchants in selecting an appropriate payment mechanism of different payment protocols for both parties. OFX is primarily designed for electronic data exchange between financial institutions and is a messaging protocol for online financial services such as Electronic Bill Presentments and Payments (EBPP) and investment services. OFX has been adopted by many large financial institutions [25]. In Australia, OFX has been implemented for BPAY, an EBPP system developed by Australian banks [9].

Internet Banking allows account aggregation. With account aggregation, customers can manage several banking accounts held at different banks via a unique access point. This means that customers just log on to the Internet Banking websites which support account aggregation enable customers to access their account held at other banks, including deposit account, credit cards and award programs [28]. To use account aggregation service, a customer has to give settings such as the URL, user name and password of each external account. Once customer logs on to an account aggregation website, this system automatically logs onto other banks' Internet Banking sites just as if a customer is logged on to them directly. With account aggregation, a customer is able to access all information from an account held at another bank. This provides customers with convenience and time saving. Although this has many advantages to the customers, security, level of information access and legal standards to protect the banks and customers has led to a slow adoption [1, 28].

In Australia, account aggregation was offered by WestPac, Commonwealth Bank, AMP and Macquarie Bank [57]. However, recently, Macquarie Bank has removed this feature due to the security concerns [47].

### 3. BENEFITS OF INTERNET BANKING

Internet Banking provides clear advantages to both the financial institutions and the customers. From the banks' perspective, Internet Banking has very low cost transactions, compared to human teller banking since it

reduces the following expenses [24, 52]: (1) Banks can reduce customer service staff as customers use more self-service functions; (2) There is less cheque processing costs due to an increase in electronic payments.; (3) Costs of paper and mail distribution are reduced as bank statements and disclosures are presented online; (4) There is less data entry as applications are completed and processed online by customers. On the other hand, according to KPMG [24], bank's revenue increases from Internet Banking due to: (1) Increased account sales; (2) Wider market reach; (3) New fee-based income; (4) New market opportunities; (5) Improved customer satisfaction. For consumers, Internet banking provides convenience, lower service charges, more accessible information about bank accounts, and an attractive option for busy people since it saves time to go to the bank branches and gives 24 hours access [26]. All the benefits of B2C e-commerce such as 24\*7 bank service, convenience, access from anywhere, one stop shop and easy access to information [57, 58 59] also apply to internet banking.

## 6. PRODUCTS AND SERVICES OFFERED ONLINE

Internet Banking provides customers with many services and several facilities to carry out online banking transactions. The basic services include opening a bank account, printing bank statement, transferring funds between bank accounts, and paying bills. Other Internet Banking services comprise of future, dated and recurring bill payments and funds transfers, loan application, e-trade, fund management, customisation of account names, ability to export banking transactions to popular financial management software packages such as Microsoft Money or Intuit Quicken [1]. In addition, account aggregation services allow customers to manage multiple accounts from different financial institutions with a single login. There are many online financial services but they can be divided into the following categories [18]: (1) Current account; (2) Insurance-based; (3) Credit-based; (4) Investment-based services.

Most Australian banks provide interactive, extensive and sophisticated Internet Banking services [6]. However, it appears that no empirical study has been conducted to examine whether the Internet banking services in Australia are satisfactory to customers.

## 7. INTERNET BANKING AND CUSTOMER BEHAVIOUR IN THE LITERATURE

In the literature, scholars have focused on examining the characteristics of Internet Banking and the factors

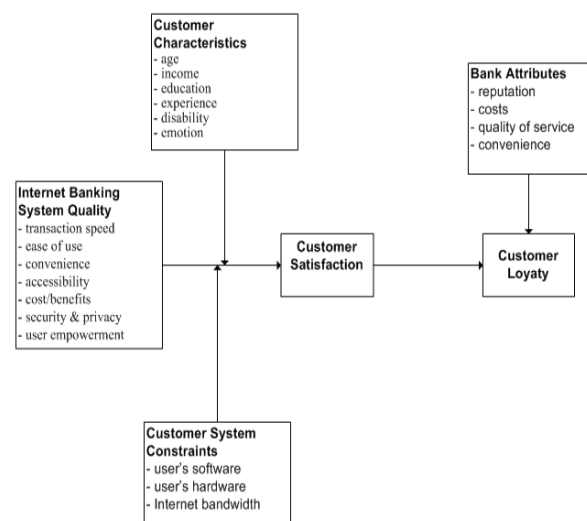

In figure 1, three groups of variables that are likely to have an impact on customer satisfaction are grouped together. These are Internet Banking system quality, customer characteristics, and customer's system constraints. However, for the purpose of assisting practitioners in building a more effective Internet

influencing Internet Banking customer behaviour/attitude. The recent studies have examined the determinants such as demographics [7, 23, 32, 49, 15, 23, 32, 49, consumer characteristics [15, 23, 32, 35, 44, 34, 37, 43, 30, 45, 51], consumer perceptions [15, 44], technology attributes [30, 45, 51], and social context [15, 44] in association with the affects of these variables to Internet Banking customer behaviour/attitude.

Unfortunately, most studies concentrated on investigating the impact of the above determinants on Internet Banking adoption. Few studies [34, 40, 48, 54] have examined customer satisfaction and loyalty in relation to Internet Banking. Though Internet Banking in Australia began in 1997 [43], literature and research have only concentrated on Australian Internet Banking adoption issues, focusing on either retail customer [43] or small and medium business [52]. No empirical study has been conducted to understand the impact of Internet Banking on customer satisfaction and loyalty in Australia.

## 8. A CONCEPTUAL MODEL AND HYPOTHESES

For the purpose of understanding the factors influencing Internet Banking customer satisfaction and loyalty, this paper proposes a conceptual model (figure 1). This conceptual model is developed based on several previous studies relating to Internet Banking and human-computer interactions [55].

**Figure 2: Conceptual model of the relationships between Internet banking system and customer satisfaction and loyalty**

banking application and the impact of the technological characteristics of Internet Banking are specially considered.

**Internet Banking system quality:** this consists of several independent variables such as transaction speed, ease of use, convenience, accessibility, cost/benefit,

user empowerment, security and privacy [30, 34, 43, 46, 54].

**Customer characteristics:** Characteristics of Internet banking customers identified from literature are younger, high income earners [17, 41, 46, 17, 41], and the better-educated [17, 41]. To date no significant relationship between e-Banking and gender or occupation has been identified [17, 41]. Zhang & Li [51] suggest that health condition (disability, emotion i.e. stress) also impact customer perceived usage of technologies. Based on the above, age, income, education, experience, disability and emotion are included as customer characteristics in the conceptual model.

**Customers' system constraints:** System constraints (hardware, software and Internet bandwidth) are likely to affect the accessibility of Internet banking by customers [51]. Customers with these constraints will be deprived of Internet banking opportunities therefore these technology issues are considered as contingent variables.

**Customer satisfaction** is defined based on the *confirmation/disconfirmation* theory that states "satisfaction results from a process of comparison where consumers judge product satisfaction against their expectations about product performance"[17].

**Customer loyalty**, in the behavioural approach, has often been construed as repeat purchase frequency [22], probability of future purchase [36] and intentions of switching brand [19]. Cunningham [11] assesses customer loyalty based on the proportion of money that a customer spends with purchases from a single supplier. In the attitudinal approach, a loyal customer must have strong "attitudinal commitment" to a brand [16, 20].

**Bank attributes:** Customer loyalty/retention may result from a bank's reputation (brand name, well-known, popularity), costs (interest rate, fees), convenience (i.e. location and distance) and quality of banking service [13]. Therefore, these factors have been taken into account to identify the relationship between customer satisfaction and customer loyalty.

From the literature review and the conceptual model, the following hypotheses are thus stated:

**H1.** Better Internet banking system quality such as the transaction speed, ease of use, convenience, accessibility, cost/benefit, user empowerment, security, and privacy is likely to have a positive impact on customer satisfaction [30, 34, 46, 54].

**H2.** The difficulties of using technology due to customer characteristics such as age, education, income, disability and emotion are likely to moderate the relationship between Internet Banking system quality and customer satisfaction [17, 41, 46, and 55].

**H3.** The limitations of accessibility to technology due to customer system constraints such as availability of software, user's system processing speed and Internet bandwidth are likely to moderate the relationship between Internet banking quality and customer satisfaction [55].

**H4.** Customer satisfaction resulting from the usage of Internet banking is likely to have a positive impact on customer loyalty [13, 34].

## 6. CONCLUSION

This is a research in progress paper, providing an overview of Internet banking, addressing a number of issues identified from literature. Literature review discussed above address Internet banking as well as online banking customer issues. The hypothesis presented above will be empirically tested to identify customer satisfaction and loyalty in internet banking. Research will be guided by the conceptual model presented above as figure 2.

## Internet Shopping Behavior among Singaporeans: Gender and Educational Issues

Hui Tak Kee, David Wan

School of Business, National University of Singapore, Singapore 117592  
{bizhutik, bizwantw}@nus.edu.sg

### ABSTRACT

The key objective of this study is to examine the influence of gender and educational level on attitudes toward online shopping. Based on a sample of 140 respondents, it was found that there is a general consensus over the convenience of the medium for information search and making purchase. Singaporeans are in general concerned with Internet privacy and security. Gender differences have a significant effect on the way respondents feel comfortable with not having the 'real' shopping experience. Both male and female respondents feel that it is easy to conduct online shopping and they generally encounter minimal problem. Finally, the perception of the Internet providing better prices and more cost savings increases with the level of education.

**Keywords:** Internet shopping, Online shopping, Net shoppers

### 1. INTRODUCTION

With the rapid advancement of new technology, all commercial activities including the retailing are affected in one way or another (Shaw, Gardner and Thomas, 1997). These changes not only create risks but also opportunities. The revolution is shaping the business world and at the same time pushing the US toward an information-based economy. In fact, the rate of technological change is so rapid that it will affect almost every aspect of how businesses are conducted. Singapore, being a small dot in the world map, is not spared.

Phau & Sui (2000) estimated that the population of Singaporean Internet shoppers to be 460,000 individuals in year 2000. This is a substantial figure given that the total population of Singapore is around four million people. The figures simply indicate that there are abundant opportunities for marketing managers who want to be a part of this growing market.

As such, understanding the attitudes, perceptions and behavior of the Singaporean Internet shopper allows the marketing professionals to efficiently target their marketing efforts. Furthermore, it also allows the marketing managers to better understand the concerns/fears of the Singaporean Internet shopper and subsequently work to address their demands and expectations. This will encourage more shoppers to shop over the Internet. This study aims to investigate the effects of gender and educational level on the attitudes of Singaporeans towards Internet shopping.

### 2. LITERATURE REVIEW

Before the age of the Internet, there have been many technological advances that influenced the operations of business transactions. The most recent technological advancement is the onset of Internet technology that

has transformed the entire business market place (Shaw, Gardner and Thomas 1997). Schwartz (1997) compared the way the Internet has changed the rules of business to the way automatic teller machines have transformed the customer's banking experience. The basis of comparison is that the customers are more comfortable doing things themselves with the ease, speed and convenience that Internet technology provides. In addition, the purchase of software over the Internet, sends the product directly into the buyer's computer and removes the olden day hassle of going to a shop, purchase the software and coming home to install it into the computer.

One of the clear advantages of shopping over the Internet is the fact that an online store does not incur the costs that a traditional store would incur. Thus costs like labor, fittings, rent and utilities are no longer relevant to an online store. As a result, products and services sold online can be priced at a cheaper rate (Lawrence, Corbitt, Tidwell, Fisher, Lawrence 1998).

There are several factors that are driving the progress of e-commerce, one of them being the increasing number of experienced users. When studying Internet shopping behavior, the familiarity of each user towards using the Internet has to be taken into consideration. Factors such as time spent on the Internet, the usage of Internet at work and the level of education all affect an individual's exposure and experience to Internet usage.

The Internet is also increasingly being used as a Customer Relationship Management (CRM) tool. CRM is not just another software or new technology but rather it deals with a more fundamental issue – unique customer needs (Geller 2002). Technology such as database management systems, using the Internet as a medium, has allowed marketers to pinpoint the individual preferences of each consumer and target

their marketing efforts in a way that appeals to the intended recipients and excludes the unintended ones.

Similar to any other innovation, companies that decide to use the Internet for marketing their offerings will need to meet or exceed the expectations of their customers to increase the likelihood of success. To this end, there are some important problems concerning the Internet's perceived security, competitiveness, impersonality and convenience that may affect the success of the companies marketing their products or services on-line.

One of the issues that consumer behaviorists have studied is the effect of time pressure on customer purchases. Research has shown that the likelihood of deferring the purchase is correlated to the effects of the pressure to make a decision in a given time as well as the type of product concerned (Dhar & Nowlis 1999). This study therefore aims to find out if time pressure affects the Internet shopper in the same way, given that while shopping over the Internet is 24hrs and in the comfort of the shopper's home environment.

Bell and Bucklin (1999) found that purchase decisions are based on the "Internal Reference Points", mainly past experience with a particular brand and product familiarity. Srivastava and Luire (2001) found that when search costs are low, the number of stores searched increases. On the other hand, if search costs are high, the consumers tend to accept the price-matching signal at face value and search less in the presence of a refund. It is thus appropriate to find out to what extent Internet shoppers value the low search costs and subsequently how that affects their buying behavior online.

One of the principle fears that consumers are facing when they are buying online concerns security and privacy (Bush, Bush and Harris 1998). The main fears relate to the possibility of the transaction intercepted by someone else (and therefore the personal particulars can be manipulated by a third party) as well as bogus or dishonest online vendor who fails to deliver the product and absconds or abuses the credit card particulars.

The effect of gender on Internet shopping is also a factor that is worth studying. Females have always been associated with a higher propensity to shop but it is the males that are found to be more involved with computer technology (Costa 1994). Internet shopping encompasses both shopping and technology and this study therefore aim to ascertain if there is a difference in attitudes between males and females towards this area. Alreck and Settle (2002) conducted a study in the U.S. and found no significant difference between the attitudes of both the male and female towards online shopping.

Another important demographic factor that is commonly used in predicting consumer attitudes is educational level. Research on this factor towards online shopping has not been particularly developed. This is probably due to the fact that the majority of the previous studies drew samples from website based surveys, thus eliciting self motivated responses from a demographically homogenous sample. In one particular census carried out in Helsinki, it was found that the higher a person's level of education, the more likely he/she uses the Internet for shopping (Statistics Finland 2002).

### 3. RESEARCH METHODOLOGY

In order to collect a random sample that would likely represent the population of Internet shoppers in Singapore, the island was classified into north, east, west and central areas. Four Mass Rapid Transit (MRT) train stations were randomly selected as target areas to conduct our survey. They are Yishun (north), Tampines (east), Boon Lay (west), and Raffles Place (central). A total of 140 surveys were collected from these four locations and the number collected from each location was equally distributed (35 surveys per MRT station). The survey was conducted at the main door of each MRT station and every 20<sup>th</sup> person was approached to participate in the survey. The collection of data was done over a period of four days (one station per day) between 1700-1900hrs. The reason for selecting this time frame was solely because of the higher pedestrian traffic during this period.

Respondents were required to complete a short (3 minutes) questionnaire that solicited their views on different aspects of Internet shopping, together with basic demographic information. The survey instrument consists of two sections. The first section comprises of twenty-eight 5-point Likert statements and the second section includes the demographic background. The construct of the questionnaire was designed to determine gender and educational level influences on a person's attitudes toward online purchase.

There are altogether 28 questions (attributes). Factor analysis was first conducted on these attributes to reduce their number to a more manageable size. Principal component analysis was used to extract the related factors first before the varimax rotation was used to further rotate for easy interpretations. Five factors were extracted. The factor scores were then used for analysis against the variables gender and educational levels in a 2-way ANOVA.

### 4. ANALYSIS AND FINDINGS

Of the 140 surveys that were conducted, 71 of them were males and 61 were females. Educational level was classified into 3 categories - Others, Intermediate and Upper. "Others" consists of those respondents with

up to secondary school level. The “Intermediate” category includes respondents having education up to junior college or diploma. Respondents who have a degree (or above) are classified under the “Upper” category.

There were 24 males (33.8%) who fell under the “Others” category, 35 (49.3%) fell under the “Intermediate” category and 10 (14.1%) in the “Upper” category. Six out of ten female respondents fell under the “Intermediate” category. There were only 12 (17.4%) and 14 (20.3%) who fell into the “Others” and “Upper” category respectively.

Of the 140 respondents, only 18 (12.9%) do not have Internet connection. 33 of the Internet users have bought online previously (14 male and 18 female). It was also found that majority of the male purchasers bought either software or multimedia products online. Online purchases of books and tickets were more prevalent amongst the females.

### Results of Factor Analysis

To reduce the 28 questions to a more manageable size, factor analysis was used to identify the key factors included in this study. The number of factors is obtained from a scree plot which shows that only 5 factors have eigenvalue of 1 or higher. The total variance explained by these five factors is 72.5 percent.

Factor 1 comprises of five questions which are related to the issue of convenience in using the Internet for shopping and so it is named as “convenience” and its variance is 16.26 percent. Factor 2 comprises of five questions relating to “security concerns” such as “confident in giving out personal particulars” and “technology reliability” and the variance of this factor is 15.96 percent. Factor 3 involves those questions that deal with “personality” (variance = 15.78 percent). Factor 4 comprises of five questions which are concerned with whether it is easy to use the Internet for shopping. The factor is named as “user experience” and its variance is 14.25 percent. Finally, the last factor is related to “pricing” (variance = 10.26 percent).

### Results of the 2-way ANOVA

The total scores of five components derived from factor analysis were tabulated against gender and educational levels. The total scores with respect to the male and female respondents are very close except for the “personality” factor where the deviation is obvious. However, for the education category, the deviations among different educational levels are more prevalent.

In this study, we would like to examine the respective role of gender and education on each factor attribute. The 2-way ANOVA technique is used for this purpose. Overall, there exist no interaction effect between

gender and educational level for all the five factors. The p-values vary from 0.16 to 0.94 (see Table 1). Therefore, this will warrant further analysis into each component. For the convenience factor, one can easily detect that there are no main effects in both gender and educational level ( $p\text{-value} > 0.05$ ). In other words, there exists no difference between the male and female respondents with respect to their perception on the convenience factor. Both groups agree that it is very convenient to shop using the Internet and this can be carried out anytime they want. The same argument applies to the different educational achievements. Regardless of their educational levels, respondents feel that it is very convenient to do their shopping via the Internet.

For security concerns, there exists no main effect for gender ( $p\text{-value} > 0.05$ ) but there exists a main effect for educational level ( $p\text{-value} < 0.01$ ). The mean score for the higher educational group is 16.75 as opposed to 12.17 for the lower educational group. In other words, the higher educational group seems to have more confidence in giving out their particulars over the Internet, as compared to the lower educational groups.

For the personality issue, main effect exists in both cases (both  $p\text{-value} < 0.01$ ). The male respondents (mean = 20.54) are more at ease with online shopping than their female counterparts (mean = 15.54). They believe that they are less likely to be hassled by the sale promoters to make purchases. They also do not mind looking up the information themselves. As for the different educational levels, it is again detected that the higher educational group (mean = 21.52) is more at ease than the lowest educational group (mean = 15.86).

For the user experience factor, no main effects are found for both gender ( $p\text{-value} > 0.05$ ) and educational level ( $p\text{-value} > 0.05$ ). It simply implies that both male and female respondents feel that it is easy to conduct online shopping and they generally encounter minimal problem. Similarly, different educational groups feel that they experience few problems in using the Internet technology.

Lastly, for the prices issue, the main effect exists marginally for gender ( $p\text{-value} = 0.08$ ). However, if the significant level is assumed to be 0.05, then there exists no main effect. In other words, both male and female respondents feel that they can get a better deal by shopping online. It also allows them to compare the prices before they make the deal. On the other hand, perceptual differences exist for different educational groups. Those with university degree or above tend to agree more on the proposition that the internet shopping website offers competitive prices and also allows them to look for the best price before they purchase (mean = 22.59).

**Table 1 Results based on 2-way ANOVA**

Source	Sum of squares	DF	Mean Square	F value	<i>p-value</i>
<b><i>Convenience</i></b>					
Gender	2.68	1	2.68	1.53	0.22
Educational level	5.28	2	2.64	1.51	0.22
G x EL	5.18	2	2.59	1.48	0.23
<b><i>Security concerns</i></b>					
Gender	2.96	1	2.96	0.86	0.36
Educational level	302.13	2	151.06	43.76	0.00
G x EL	13.05	2	6.52	1.89	0.16
<b><i>Personality</i></b>					
Gender	705.83	1	705.83	62.27	0.00
Educational level	331.32	2	165.66	14.62	0.00
G x EL	38.89	2	19.44	1.72	0.18
<b><i>User experience</i></b>					
Gender	2.41	1	2.41	0.12	0.73
Educational level	20.65	2	10.33	0.50	0.61
G x EL	51.27	2	25.63	1.25	0.29
<b><i>Prices</i></b>					
Gender	18.35	1	18.35	3.10	0.08
Educational level	260.47	2	130.23	21.97	0.00
G x EL	0.79	2	0.40	0.07	0.94

In sum, there exists no interaction effect between the gender and the educational level in all the issues examined. For gender, main effect exists in the “personality” issue only. For educational level, main effect exists in 3 out of 5 cases, namely, “security concerns”, “personality” and “prices”.

## 5. DISCUSSION AND CONCLUSION

The main objective of this study is to examine the influence of gender and educational level on attitudes toward buying or consider buying over the Internet. The high means for the convenience factor showed that there was a general consensus among the respondents that the Internet is a convenient medium for information search or making purchase, taking into the account that the Internet spans international boundaries and is available 24hrs a day. This was indicative of individuals with different educational levels and of both gender groups.

However, Singaporeans in this study registered low means for security concerns regardless of gender or educational level. This can be attributed to the fact that Internet privacy and transactional systems are still in its infancy stages locally. With the recent spate of Internet

crimes involving banks and tampering of private information, the concern of revealing personal information on the Internet is reflected here. In addition, better-educated respondents seemed to be less concerned about security issues. This could be explained by the fact that better-educated individuals spend more time on the Internet. Thus familiarity levels and trust towards Internet security are higher as a result. This opens an avenue for companies tapping the local Internet market to design alternative strategies for market segmentation based on educational levels.

The personality factor measured the extent to which individuals are comfortable with not having a ‘real’ shopping experience, where physical touch and enjoyment enhance the shopping process. Gender differences were shown to have a significant effect on this factor. Females indicated a dislike for not being able to savor a physically shopping experience online while males did not mind that much. This of course could be very product specific as women often purchase clothes; cosmetics while the males tend to purchase more on products like software and financial services. This might serve as a working platform for Internet companies wanting to target the female consumer market. The lack of physical touch could be

substituted with a more interactive website, providing more information, or even making use of new internet technology like virtual tasting and touching.

The study also found that higher educated individuals are less likely to be affected by the personality factor. This is especially so for those who are higher educated. This can probably be attributed to the fact that the higher educated individuals spend more of their time at the work place and have less time to conduct physical shopping. They might also possess better information and knowledge on products and services they intend to purchase, and thus feel safe about not having to have physical feel or personal contact in the buying process.

No significant effect was detected for user experience for both gender and educational groups. User experience measured the perception of usability and usefulness of the Internet in general and a high total mean score indicated that Singaporean users are generally satisfied with the functions provided by the Internet. The fact that this is consistent through gender and all educational levels could indicate high Internet penetration rate among Singaporeans across the board. This is reflected in our data set where 87.1% of the respondents have Internet connection and six in ten users use the Internet for product information search. With the high Internet literacy rate and satisfactory user experience, there is a vast pool of consumers for which Internet companies could work on to identify their niches.

The study also predicts that educational levels would have an effect on the perception of pricing on the Internet. The perception of the Internet providing better prices and more cost savings increased with the level of education. In this study, the characteristics of people who actually search the Internet for information might provide a clue. Most of the respondents who claim they use the Internet for information search belong to the immediate or upper educational levels. The fact that they use the Internet for information search gives more opportunities for price comparisons as compared to those who do not do so. It is also noteworthy that web based businesses are able to offer more attractive prices due to reductions in capital costs of a physical operating outlet.

## ABSTRACT

This paper focuses on users' behavior towards an EC website. A novel Markov Chain-based way combining the web log file information and the topology of an EC website is presented to rank a user's interest in a WebPage. Then a URL-USERID relevant matrix is set up, with URL taken as a row and USERID as column, and each element's value is the probability of a user to access a WebPage when time goes infinitely. The similarity of each column vector can be used to cluster customers, and relevant web pages can be found from the similarity of each row vector. The knowledge discovered by this dynamic model can be fairly helpful to the design and maintenance of a website, to provide personalized service, and can be used in an effective recommending system of an EC website etc.

**Keywords:** Markov chain, electronic commerce, customers clustering, WebPages clustering

## 1. INTRODUCTION

With the high development of Internet, Web-based applications have been warmly welcomed. For instance, Remote Education, Network Bank, and in particular, the Electronical Commerce(EC) based on Internet have been increasing quickly. When a customer is browsing an EC website, his behavior information will be collected by the Web Server automatically, and stored in a weblog file. On the other hand, the topology of website's WebPages indicates some relationship between WebPages. If knowledge can be discovered from the weblog and the structure of an EC website, it can do good to the design and maintenance of a website, and provide personalized service, and Customer Relationship Management (CRM) can be conducted effectively. In a word, it can lead an EC website to succeeding in today's competitive business market. Customers clustering and WebPages Clustering are one of the most important issues in discovering knowledge from the Web. They are the preconditions for most web-based applications.

Intuitively, when time goes infinitely, users' ultimate probability of browsing each WebPage is a constant, and it should reflect the worthiness of each page to the users. This hypothesis is proved in this paper, and this has potential use in web-based data mining. Firstly, a user's behavior is abstracted as a homogeneous Markov Chain dynamically, which then is proved to be ergodic. Secondly with the help of the ergodic Markov Chain, a novel way to evaluate a user's interest in a WebPage combining the weblog and the structure of an EC website is presented. Lastly, a URL-USERID relevant matrix is set up, where URL is taken as a row and USERID is taken as column, and each element's value is the probability of a user to access a WebPage when time goes infinitely. Relevant WebPages and similar customers can be clustered efficiently by using the URL-USERID matrix.

This paper is organized as follows: Section 2 presents the necessary mathematical knowledge. The model of a user's behavior is presented in Section 3.

Section 4 presents the way to cluster the WebPages and customers. Section 5 concludes this paper and discusses the direction of the future research.

## 2. MATHEMATICAL BACKGROUND

**Definition 2.1** Suppose the state space  $\{S=i_0, i_1, i_2, i_3, \dots\}$  of the random variables  $\{x(t), t=0, 1, 2, \dots\}$  is discrete; for only time  $t$  and any state space  $i_0, i_1, i_2, \dots, i_{t-1}, i_t, j$ , the equation:

$P\{x(t+1)=j, x(t)=i, x(t-1)=i_{t-1}, \dots, x(0)=i_0\} = P\{x(t+1)=j | x(t)=i\}$  is always true, then  $\{x(t), t=0, 1, 2, \dots\}$  is named a Markov chain.  $P\{x(t+1)=j | x(t)=i\}$  (abbreviated to  $p_{ij}(t)$ ) represents the probability of transition from the state  $i$  to  $j$  at the time  $t$ . If the transition probability  $p_{ij}(t)$  is independent of  $t$ , i.e., for any  $i, j \in S$  and any different time  $t_1, t_2$ ,  $p_{ij}(t_1) = p_{ij}(t_2)$ , then this Markov chain is called homogeneous.

**Definition 2.2**  $P=(p_{ij})_{n \times n}$  is one step transition probability matrix of this homogeneous Markov chain, where

- (1)  $p_{ij} \in (0, 1) \quad 1 \leq i, j \leq n$
- (2)  $\sum_{i=1}^n p_{ij} = 1 \quad j = 1, 2, 3, \dots, n$

**Definition 2.3** Suppose  $\{x(t), t=0, 1, 2, \dots\}$  is a homogeneous Markov Chain on the state space  $S$ , the probability  $p_{ij}(k) = P\{x(t+k)=j | x(t)=i\}, i, j \in S$  represents the system will transit from state  $i$  to state  $j$  after  $K$ th step which is called  $k$ -step probability. And the matrix  $P=(p_{ij}^{(k)})_{n \times n}$  is named  $k$ -step transition matrix, where

- (1)  $p_{ij}^{(k)} \in (0, 1) \quad 1 \leq i, j \leq n$
- (2)  $\sum_{i=1}^n p_{ij}^{(k)} = 1 \quad j = 1, 2, 3, \dots, n$

### 3. MODELING A USER'S BROWSING BEHAVIOR

For a virtual user A,  $R=\{r_1, r_2, \dots, r_n\}$  denotes the set of URLs of an EC website, and  $S$  is considered as the space state. At time  $t$ , the user A is browsing the URL  $r_i$  in the probability  $p_i(t)$ , and will leave for the URL  $r_j$  in probability  $p_{ij}(t)$ . The user's surfing action on the web can be abstracted as a homogeneous Markov Chain, if  $p_{ij}(t)$  is independent of time  $t$ .

**Theorem 1** Suppose  $\{x(t), t=0, 1, 2, \dots\}$  is a homogeneous Markov Chain on the state space  $S$ , for  $m \geq 1$ ,  $n \geq 1$  and  $k=m+n$ , the following is true.

$$p_{ij}(k) = \sum_{r \in S} p_{ir}(m) p_{rj}(n) \quad i, j \in S \quad (3-1)$$

Eq.(3-1) is the famous Chapman-Kolmogorov equation. This equation denotes that if a user wants to move from space  $i$  to space  $j$  by  $(m+n)$  steps, he must move to any space  $r$  by  $m$  steps and then move to space  $j$  by  $n$  steps.

The matrix form of this theorem is  $P_{m+n} = P_m \cdot P_n$ . Generally  $P_n = P_1^n$  can be got. From the equation, the  $n$ -step transition matrix of homogeneous Markov Chain can be calculated by one step transition Matrix.

**Theorem 2** At time  $t$ , a Markov Chain's distribution vector  $p(t)$  is totally determined by the initial distributed vector  $p(0)$  and one step transition matrix, that is  $p(t) = p(0)P^t$ .

#### 3.1 Analysis of user's interest in WebPages

How to evaluate the importance of a WebPage and a user's interest in the WebPage is crucial to web data mining. As the user's interest in a WebPage is concerned, it should at least include the following metrics:

**Relevance:** It's an intuitive metric, denoting how much the user cares about the WebPage. It has been used as a useful metric in today's most Web Search Engine.

**Authority:** The authority metric means how many WebPages refer to the WebPage  $r$ . Moreover, the Web resources referred by higher quality resources should be assigned with higher authority.

**Hub:** The hub metric means how many WebPages are pointed by the Web resource  $r$ . Moreover, the Web resources pointing to higher quality resources should be assigned with higher hub.

**Novelty:** It denotes that how much a WebPage differs from other WebPages.

#### 3.2 User's Browsing Behavior

Suppose that a user is browsing the WebPage of an EC website, his behavior is as follows. At time  $t$ , he is browsing the WebPage  $r_i$  and at next time  $t+1$ , he may have one of the following options:

(1) Continue browsing the WebPage  $r_i$

(2) Click one hyperlink in  $r_i$  to jump to a new URL  $r_j$ ;

(3) Press the "BACK" button in the browser so as to return to the last browsing WebPage;

(4) To enter a new URL of the website.

Towards each options above, the probability of a user's tendency is measured as  $\alpha, \beta, \gamma, \delta$  respectively, which satisfies the condition  $0 < \alpha, \beta, \gamma, \delta < 1$ ,  $\alpha + \beta + \gamma + \delta = 1$

#### Definition 3.1 Web Graph

The linkage structure graph of the WebPages,  $G=(V, E)$ , is a directed graph, where  $V$  is the set of nodes ( $|V|=n$ ), a node corresponds to a WebPage, for instance, in  $R$ ; and  $E$  is the set of edges,  $E=\{(w_i) | v_i, v_j \in V \text{ and WebPage } v_i \text{ points to } v_j \text{ through hyperlink}\}$ .

#### Definition 3.2 Tendency Matrix

The Tendency Matrix of resources  $R$  is  $U = (u_{ij})_{n \times n}$  and

$$u_{ij} = \begin{cases} \alpha & i = j \\ \beta & (v_i, v_j) \in E \\ \gamma & (v_j, v_i) \in E \\ \delta & \text{otherwise} \end{cases} \quad (3-2)$$

It is noted that the Tendency Matrix here has synthesized the four metrics ( $\alpha, \beta, \gamma, \delta$ ) mentioned above (Relevance, Authority, Hub and Novelty). With the tendency matrix being normalized, one-step transition probability matrix in the Markov Chain for a user's surfing behavior on the EC Website can be got.

#### Definition 3.3 One Step Transition Matrix

One step transition matrix of a virtual user A on the resource  $R$  can be defined as  $P = (p_{ij})_{n \times n}$ , and each element of  $P$  is as follows:

$$p_{ij} = \frac{u_{ij}}{\sum_{j=1}^n u_{ij}} \quad i = 1, 2, \dots, n \quad (3-3)$$

The distribution vector  $p(t)$  can be calculated by theorem 2 and definition 3.3. It's obvious that  $\alpha, \beta, \gamma, \delta$  actually reflect the relative importance, in the user's opinion, of relevance, authority, hub and novelty metrics respectively. And thus  $\alpha$  is called relevance parameter,  $\beta$  authority parameter,  $\gamma$  hub parameter and  $\delta$  novelty parameter.

#### 3.3 Stationary distribution of a Markov Chain

**Definition 3.4** Suppose that  $S$  is the state space of one homogeneous Markov Chain  $\{x(t), t=0, 1, 2, \dots\}$ , if for any  $i, j \in S$ , there exists a constant  $\mu_{ij}$  which is independent of  $i$ , making the following equation always true. then the Markov Chain is ergodic.

$$\lim_{t \rightarrow \infty} p_{ij}(t) = p_j$$

**Theorem 3**

A homogeneous Markov chain, on the state space  $S=\{s_1, s_2, \dots, s_n\}$ , is ergodic, if for any  $s_i, s_j \in S$ , there exists a positive integer  $k$ , the state can transit from  $s_i$  to  $s_j$  via the edge between  $s_i$  and  $s_j$  in a positive probability within  $k$  steps, that is

$$\lim_{k \rightarrow \infty} p_{ij}^{(k)} = p_j$$

where  $p_j(j=1,2,\dots,n)$  is the unique solution to the following equation:

$$p_j = \sum_{i=1}^n p_i p_{ij} \quad (j = 1, 2, 3, \dots, n) \quad (3-4)$$

which satisfies the restricted (3-5) conditions.

$$\begin{aligned} p_j &> 0 \quad (j = 1, 2, \dots, n) \\ \sum_{j=1}^n p_j &= 1 \end{aligned} \quad (3-5)$$

Theorem 3 denotes that when a homogeneous Markov Chain is ergodic, the distribution vector  $p(t)$  is only determined by one step transition matrix, independent of time  $t$  and of its initial vector  $p(0)$ .

**Definition 3.5 Positive Stochastic Matrix**

Suppose  $P=(p_{ij})_{n \times n}$  is an  $n$ -dimensional non-negative matrix, if it satisfies the following two conditions: ① the sum of all elements in each row is 1 ② if there exists positive integer  $k$ , making  $P^k > 0$ , then the matrix  $P$  is called positive stochastic matrix.

It is true without proof that each element in one-step matrix is positive and the sum of each row is 1, respectively. So one step matrix is positive stochastic matrix.

**Theorem 4** A Markov Chain on the finite State Space  $S=\{s_1, s_2, s_3, \dots, s_n\}$  is ergodic if and only if its transition matrix is positive stochastic matrix.

In a word, with the help of formulas (3-4) and (3-5), the ultimate probability can be got easily. Suppose the user  $A$  is rational and experienced enough in an EC website, the probability of browsing the WebPages should be proportional to its worthiness. In real life, user usually spends more time with the WebPages he cares more. Firstly, since the user has no knowledge about the value of each WebPage, he browses WebPages randomly. The user becomes more and more experienced while more and more WebPages he browsed. So his judgment on the value of WebPages becomes more and more accurate. When time goes infinitely, the ultimate probability of browsing each WebPage should reflect the worthiness of each WebPage to the user accurately. From Theorem 3, the ultimate distribution vector  $p(t)$  of a ergodic Markov chain is independent of the initial distribution vector  $p(0)$ , but totally determined by the one step

transition probability matrix. So given an EC Website WebPages  $R$ , the transition probability matrix can be set up through definition 3.3, and the ultimate distribution vector can be calculated based on Theorem 3. The ultimate distribution vector is user's interest in WebPages. The group of equations in Theorem 3 can be solved using "Gauss method". The ultimate constant probability of user's browsing the web can be used to discover the similar customers and relevant WebPages.

## 4. CUSTOMERS CLUSTERING AND WEBPAGES CLUSTERING

### 4.1 Data Preparation

An EC website and the weblog file will be used in knowledge discovering. The weblog file complies with W3C standard. It at least includes the following items:

① user's IP address; ② Access time; ③ Request method; ④ the URL of the accessed WebPage; ⑤ the transferred protocol; ⑥ return code; ⑦ the bytes transferred. Before discovering knowledge from weblog, data preparation is needed. It has two stages: data cleaning and transaction identification. Suppose  $L$  is a weblog, and  $I$  belongs to  $L$ . The items of  $I$  are, respectively,  $I.ip$ ,  $I.uid$  and  $I.url$ . The algorithm to find a transaction is as follows:

Step1: to partition weblog by the user's IP address, that is to determine each visitor's browsing set;  
Step2: to calculate the times of each customer's browsing each WebPage in every set;  
Step3: to sort the browsing set by IP address, and then the users' browsing set can be got.

### 4.1.1 Topology of an EC website

A website's topology is a directed graph, and customer's browsing pattern is its subgraph. The customers who have similar visiting subgraphs are similar. Suppose that an EC website's topology is as the following directed graph:  $G=(N, N_p, E)$ , where  $N$  is the set of nodes,  $N_p=\{Node \in N, \{userid, p\}^n \mid n \geq 1\}$  stores the customers' USERID and the ultimate probability to browse each Webpage, which can be calculated by theorem 3.  $N$  is the attribute of node;  $E$  is the set of edges. From the set  $N$  of  $G$ , all the urls of the EC website can be got. And from the each node's userid and his ultimate probability to visit this WebPage can be found. According to this, a URL-USERID relevant matrix  $M_{m \times n}$  can be set up as follows:

$$M_{m \times n} = \begin{bmatrix} p_{11}, p_{12}, \dots, p_{1n} \\ M \\ p_{m1}, p_{m2}, \dots, p_{mn} \end{bmatrix}$$

Analysis of the matrix can be made as follows.

- (1) Each element  $p_{ij}$  of this matrix presents the probability of the  $j$ th customer's to visit the  $i$ th URL when time goes infinitely.
- (2) The  $i$ th row vector represents that the probabilities

of the customers to visit the  $i$ th URL when time goes infinitely.

- (3) The  $j$ th column vector represents the probabilities of the  $j$ th user to visit each URL when time goes infinitely. And the other form of matrix  $M_{m \times n}$  can be written as  $M = (p_1, p_2, \dots, p_n)$ .

At the same time, URL-USERID relevant matrix can be represented by row vectors, and each row vector is of a constant. So a conclusion can be drawn that the row vectors represent the structure of the EC website and also imply the common browsing pattern; the column vectors represent the types of customers and the personalization browsing pattern. The similarity of each row vector represents the relevant WebPage and the similarity of each column vector represents the similar customers. The similarity can be judged by the definition 4.1. The larger value of the angle of between vectors  $a$  and  $b$ , the more similar they will be. In practical use, a threshold can be set to determine the similarity. Definition 4.1 Suppose vectors  $a = (a_1, a_2, \dots, a_n)$  and  $b = (b_1, b_2, \dots, b_n)$ , then, the cosine of the angle between vectors  $a$  and  $b$  is

$$\cos(a, b) = \frac{a \cdot b}{|a| \cdot |b|} = \frac{(a_1 \cdot b_1 + a_2 \cdot b_2 + \dots + a_n \cdot b_n)}{\sqrt{a_1^2 + a_2^2 + \dots + a_n^2} \cdot \sqrt{b_1^2 + b_2^2 + \dots + b_n^2}}$$

#### 4.1.2 One-Step Matrix and Ultimate Probability

Four metrics described in Section 3 can be used to evaluate the interest of a user in a WebPage during given time  $t$ . Times of the user's visiting the WebPage represent the relevance of a user to a WebPage. The inverse of a url's Indegree (the number of hyperlinks pointed to the URL) represents the authority; the Outdegree (the number of hyperlinks pointing to the other URL) of the url represents the hub of a url; the novelty can be judged by the inverse of the Indegree of a url approximately. The detailed method is as following.

Firstly, the trend matrix  $U = (u_{ij})_{m \times n}$  (at time  $t$ ) is formed by the following

$$u_{ij} = \begin{cases} \alpha & i = j \\ \beta & (v_i, v_j) \in E \\ \gamma & (v_j, v_i) \in E \\ \delta & \text{otherwise} \end{cases}$$

Secondly, the following is defined

$$\begin{aligned} a &= p_1 \times \frac{I_i^t \cdot \text{time}}{\sum_{i=1}^m I_i^t \cdot \text{time}} & b &= p_2 \times \frac{\text{outdegree}(v_j)}{|E|} \\ c &= p_3 \times \frac{\text{indegree}(v_i)}{|E|} & d &= p_4 \times \frac{1}{\text{indegree}(v_i)} \end{aligned}$$

Third, normalizations of  $a, b, c, d$  is as follows,

$$a = \frac{a}{\sqrt{a^2 + b^2 + c^2 + d^2}} \quad b = \frac{b}{\sqrt{a^2 + b^2 + c^2 + d^2}}$$

$$c = \frac{c}{\sqrt{a^2 + b^2 + c^2 + d^2}} \quad d = \frac{d}{\sqrt{a^2 + b^2 + c^2 + d^2}}$$

respectively.

let

$$\alpha = a^2 \quad \beta = b^2 \quad \gamma = c^2 \quad \delta = d^2$$

It can be noticed that

- (1)  $p_1, p_2, p_3$  and  $p_4$  ( $p_1, p_2, p_3, p_4 > 0$ ) are coefficients.
- (2) If the outdegree or indegree of a node is zero, then let the outdegree or indegree is 1.
- (3) It is obvious that  $a, b, c, d$  can be adapted by the coefficients  $p_1, p_2, p_3, p_4$ .

#### 4.2 Customer clustering and WebPages clustering

With the help of the above URL-USERID matrix, clustering can be done in an EC website.

##### 4.2.1 Customers Clustering

As described above, the column vector  $(p_1, p_2, \dots, p_n)$  of relevant matrix  $M_{m \times n}$  is the personalized browsing pattern. The customers who have similar browsing patterns can be clustered as similar customers. The cosine of the angle between the two column vectors can be calculated by definition 4.1 to cluster similar customers. In order to cluster the similar customers, a matrix  $Q$ , of which each element is the cosine of the angles between two column vectors, can be formed. It's obvious that the matrix  $Q$  is symmetrical, i.e.  $Q = (q_{ij})_{n \times n}$ ,  $q_{ij} = q_{ji}$ ,  $q_{ii} = 0$ . The matrix  $Q$  is as follows:

$$Q = \begin{bmatrix} 0 & q_{12} & \dots & q_{1n} \\ q_{21} & 0 & \dots & q_{2n} \\ \dots & \dots & 0 & \dots \\ q_{n1} & q_{n2} & \dots & 0 \end{bmatrix}$$

A threshold is given by formula (4-1)

$$\theta = \frac{2 \times \sum_{i=1}^{n-1} \sum_{j=i+1}^n q_{ij}}{n \times (n-1)} \quad (4-1)$$

The threshold is the average of all elements in matrix  $Q$ , and it can be adapted to satisfy the requirements in practical usage. For any  $i, j \in Q$  ( $1 \leq i \leq n, i < j \leq n$ ), if  $q_{ij} > \theta$ , then the  $i$ th customer and the  $j$ th customer can be clustered into the same group. The more the threshold is, the more accurate the clustering can be.

All in all, any two customers can be clustered if the similarity of their ultimate probability to each WebPage vector satisfies the given threshold. In our daily life, as

time goes by, the similar customers will come into being after their long browsing and transaction. The method proposed in this paper can track this procedure and grasp the trend of this procedure.

complexity and time complexity are  $O(n)$ . When similar customers are to be discovered, it is only needed to evaluate the similarity of the two  $n$ -dimension vectors. Both space complexity and time complexity are  $O(n)$ .

#### 4.2.2 WebPages clustering

As has been said that the row vectors represents what all the customers have browsed each WebPage of an EC website. If all the customers have the similar experience in some WebPages, then these WebPages will be thought as relevant WebPages. A matrix  $Q'$  is introduced, elements are the cosines of the angles of between row vectors. For ease usage, let  $q'_{ij} \in [0, 1]$  (if  $i=j$ ). The matrix  $Q'$  is as follows:

$$Q' = \begin{bmatrix} 0 & q'_{12} & \dots & q'_{1m} \\ q'_{21} & 0 & \dots & q'_{2m} \\ \dots & \dots & \dots & \dots \\ q'_{m1} & q'_{m2} & \dots & 0 \end{bmatrix}$$

The threshold can also be calculated by formula (4-1) and adapted according to the requirements. For any  $q'_{ij} \in Q'$  ( $1 \leq i \leq m, i < j \leq m$ ), if  $q'_{ij} > \theta$ , then the  $i$ th URL and the  $j$ th URL ( $j \in [i, m]$ ) can be considered as one group.

In a word, if all the customers browse a given WebPage, their ultimate probability of the WebPage is a constant. The row vectors of URL-USERID are also constants. For two different WebPages, if all the customers' probabilities of browsing them are the same or similar, it is reasonable that they are relevant WebPages.

#### 4.3 Algorithm analysis

The method proposed in this paper to cluster relevant WebPages and similar customers is based on Markov Chain, which combines the weblog file and website topology. The way to evaluate a user's interest in a WebPage has integrated four metrics: Relevance, authority, hub and novelty. The linear equations can be used to calculate user's interest in WebPages. When WebPages are clustered, we only need to evaluate the similarity of the two  $n$ -dimension vectors. Both space

#### 5. CONCLUSION

A Markov Chain-based dynamic model is put forward to investigate the customers' browsing behavior towards an EC website. As is well known that the similar customers will come into being after their long browsing and transacting with a EC website as time goes by. It is assumed that the ultimate probability of browsing each WebPage reflects the worthiness of each WebPage when time goes infinitely, and, thus, this probability is a constant. A URL-USERID relevant matrix is set up to cluster customers and WebPages. This novel method can be integrated in an EC recommending system and in personalized service system. That will be our further research interest.

## ABSTRACT

This study models innovation diffusion process with brand-level competition, focusing on the competition among ADSL service providers in Japan. For a particular brand (service provider), the diffusion process is assumed to be influenced by three forces: (1) the external influence through mass media, (2) the internal influence of the communication with the brand adopters, and (3) the influence due to the market growth of the product category. Through the assumption that the internal influence of each brand in a product category has the identical structure, the proposed brand-level model can be summed up to the Bass model of the product category, and solved with a closed-form expression. Applying the model to the diffusion of ADSL market in Japan, the empirical results reveal that the proposed model describes the brand-level diffusion patterns very well.

**Keywords:** ADSL service, diffusion process, competition, Bass model

## 1. INTRODUCTION

Following the success of the Bass model (1969), marketing researchers have developed different types of diffusion models to address various issues concerning the sales growth of new products (Krishnan, Bass, and Kumar 2000). These issues include analyzing the role of marketing-mix variables in the diffusion process, developing multi-product interaction diffusion models, investigating the innovation diffusion process in multi-markets, and so forth. However, most of the models focus only on category-level diffusion problems. For companies such as Intel and Microsoft that hold near-monopoly positions in their respective markets, the category-level sales growth is of primary concern. But in industries such as minivans and cellular-phones with severe competition, brand managers are likely to pay attention to understanding the sales growth at the brand-level.

The diffusion literature recognizes that all categories evolve from a centralized diffusion process, initially dominated by a monopolist, into a decentralized process having many competitors (Rogers, 1995). Cross-brand or competitive interpersonal influence was first investigated in the marketing literature by Peterson and Mahajan (1978). They proposed a system of equations for different types of multiple product interactions including complement, substitute, and contingent. Since the 1990s, researchers have proposed several models to describe brand-level innovation diffusion process. Currently, researches on brand-level innovation diffusion are not sufficient and always concern a special problem. As pointed out by Chatterjee, Eliashberg, and Rao (2000), there are opportunities for empirical researchers to work on competitive diffusion model specifications across product and service categories and across competitive positions within categories.

The paper first reviews the past researches about the brand-level innovation diffusion. Then a competitive diffusion model is proposed and applied to the diffusion of ADSL subscribers in Japan, followed by some managerial implications and limitations.

## 2. BRAND-LEVEL DIFFUSION MODELS

Mahajan, Sharma, and Buzzell (1993) extended the Bass model to assess the impact of new-brand entry on market expansion of the incumbent brands as well as the whole market. Specifically, they introduced a new interaction term to capture the internal influence of one brand's growth through drawing adopters from other brands' potential adopters. The model was illustrated by applying it to the Polaroid and Kodak case in instant photography industry from 1976 to 1985. The model was estimated under the assumption that the intensity of internal influence is identical for all brands. Estimation results suggest that the model is appropriate for the Polaroid and Kodak case.

Parker and Gatignon (1994) developed a framework to provide a systematic analysis of alternative specifications for brand-level first purchase diffusion. They started with a general specification in which the brand-level adoption is a function of diffusion effects, price and advertising, and suggested four types of brand-level diffusion processes depending on the nature of interpersonal communication and brand-level competition. They have evaluated these specifications by estimating these four models on brand trial data in a new packaged goods category, using the NLS procedure. The results showed that no one specification appeared to dominate others across brands, and the effectiveness of the models appeared to be significantly different across brands.

Givon, Mahajan, and Muller (1997) provided an example of a competitive brand level diffusion model with a more specific focus than Parker and Gatignons' (1994) work. In a competitive extension to their earlier model (Givon, Mahajan, and Muller 1995), the authors investigated the implications of piracy in a duopolistic software market. The market dynamics are captured in a framework that extends the Bass model to incorporate brand switching as well as legal and illegal uses of the competing software brands. This modeling approach was used to analyze the diffusion of Lotus 1-2-3 versus Other Spreadsheets and WordPerfect versus Other Word Processors in the United Kingdom. The results showed that for Lotus 1-2-3 the users were likely to switch to Other Spreadsheets than vice versa, and for WordPerfect the users were likely to influence the users of Other Word Processors to switch than vice versa.

Krishnan, Bass, and Kumar (2000) proposed a model to analyze the impact of later entrant on the sales growth and diffusion speed for the whole category as well as for the incumbent brands. The authors supposed that two brands were presented in the market from the time of introduction. When the third brand was introduced, the market potential of the whole category would expand and the category market would start diffusing faster. Furthermore, the diffusion speed of the incumbent brands might be affected either positively or negatively depending on the model parameters. The model was applied to the cellular phone industry of six markets in the United States from 1983 to 1996. The results revealed that the effects of the third entry on incumbent brands and total category were different across markets.

Past researches on brand-level innovation diffusion have provided limited knowledge to understand both of the brand-level growth pattern and the relationships among brands. Researchers have made efforts to specify model parameters appropriate for special cases. All these models seem appropriate for the special cases in their works. However, the models cannot be solved in closed-form expressions, which made researchers employ discrete formulations to estimate continuous diffusion processes. This would result in the estimation bias and decrease the attractiveness of the models. Krishnan, Bass, and Kumar (2000) proposed a brand-level diffusion model for investigating the effects of a new entrant on diffusion speed and market potential for both the incumbent brands and the whole product category. Although their model has a closed-form solution, it did not incorporate the competitive effect among brands directly.

### 3. THE PROPOSED DIFFUSION MODEL

The concept underlying the Bass model is the assumption that the diffusion of an innovation is stimulated by two forces: (1) the external influence such as the mass media, and (2) the internal influence such as the communication between adopters and potential

adopters. For a particular brand in a product category, the brand-level diffusion may be affected by three forces: (1) the external influence through mass media, (2) the internal influence through adopter-nonadopter communication of the brand, and (3) the influence from the growth of product category (Nakajima, 1990). Hence, given that there are  $n$  brands in a product category, the diffusion process of the brand  $j$  ( $j=1, \dots, n$ ) can be expressed as follows:

$$f_j(t) = (1 - F(t))(p_j + q_j F_j(t) + r_j F(t)) \quad (1)$$

where  $F(t)$  and  $F_j(t)$  are the cumulative adoption distribution for the product category and brand  $j$ , respectively.  $f_j(t)$  is the p.d.f. of adoption for brand  $j$ . The term  $p_j(1-F(t))$  captures the adoption due to external influence for brand  $j$ , and  $q_j F_j(t)(1-F(t))$  captures the adoption due to internal influence of brand  $j$ . The parameters  $p_j$  and  $q_j$  represent external and internal coefficients, respectively, which are the same as those in the basic Bass model. The term  $r_j F(t)(1-F(t))$  in the above equation represents the adoption due to the influence of the growth of the whole product category on brand  $j$ . For each brand, the influence from the maturity of total market may be different. This difference is captured by the parameter  $r_j$ .

It is common that the success of product category would influence the adoption of a particular brand in several ways, such as communicating the positive information about the product category, decreasing the uncertainty of the product, and so forth. Although brand-level communication would be the main force impacting the subsequent adoption of that brand, the effect of the cumulative adoption level of product category must be considered. Note that in equation (1), the adoption for brand  $j$  comes from the rest of the whole market potential, that is,  $1-F(t)=1-\sum F_i(t)$ . As Krishnan, Bass, and Kumar (2000) has pointed out, when consumers make decision to buy a new product, the question of "what brand to buy" would be only the secondary to the "whether or not to buy the product" question. In this case the category effect is likely dominant and the specification of market potential for each brand may not be suitable. If the category effect is not dominant, in contrast, the adoption for brand  $j$  can be expected to come only from  $1-F_j(t)$  as in Mahajan, Sharma, and Buzzells' model (1993). In effect, for analyzing category-level diffusion, the Bass model (1969) which focuses on  $f(t)/(1-F(t))$  should be used. On the contrary, for analyzing the brand-level diffusion, in which the category effect dominates the brand-level effect in consumer's buying behavior,  $f_i(t)/(1-F(t))$  should be considered.

Summing up the both sides of equation (6) including all brands yields:

$$\sum_j f_j(t) = (1 - F(t))(P + \sum_j q_j F_j(t) + R F(t)) \quad (2)$$

where  $P=\sum_j p_j$ ,  $R=\sum_j r_j$ . Furthermore, assuming that the intensity of internal communication effect for each brand in the product category is identical, that is,  $q_j=Q$ ,

the above equation results in the category Bass model (Bass 1969):

$$f(t) = (1 - F(t))(P + (Q + R)F(t)), \quad f(t) = \sum f_i(t). \quad (3)$$

And for brand  $j$ ,

$$f_j(t) = (1 - F(t))(p_j + Qx_j + r_j F(t)). \quad (4)$$

Thus, the cumulative diffusion rate  $F(t)$  can be easily solved as a function of time  $t$ :

$$F(t) = \frac{1 - C \cdot e^{-(P+Q+R)t}}{1 + (Q + R) / P \cdot C \cdot e^{-(P+Q+R)t}} \quad (5)$$

$$C = \frac{1 - F_0}{1 + (Q + R)F_0 / P}, \quad F_0 = F(0). \quad (6)$$

Substituting  $F(t)$  into the brand level equation (4) and then it can be solved to yield  $F_i(t)$  as a function of time:

$$F_j(t) = \frac{Pr_j - p_j R}{QR} + \frac{r_j}{R} F(t) - K_j \left( F(t) + \frac{P}{Q + R} \right)^{Q/(Q+R)} \quad (7)$$

$$K_j = \frac{r_j}{R} \left( F_0 + \frac{P}{Q + R} \right)^{Q/(Q+R)} - \left( F_{j0} + \frac{p_j}{Q} - \frac{r_j P}{Q(Q+R)} \right) \times \left( F_0 + \frac{P}{Q + R} \right)^{Q/(Q+R)}, \quad F_{j0} = F_j(0) \quad (8)$$

Unlike the model proposed by Krishnan, Bass, and Kumar (2000), the model proposed here incorporates the effects of category growth on adoption for a particular brand directly. The parameter  $r_j$  represents the intensity of influence of the growth of product category on brand  $j$ , and  $r_j$  may differ across brands. This turns to be important when considering the brand-level innovation diffusion issues. Furthermore, the brand-level model proposed here can be summed up to the Bass model (1969). This gives validity to the proposed model because the Bass model has a strong behavioral basis and has found excellent empirical support over a wide range of products (Mahajan, Muller, and Bass 1993). The assumption that  $q_i = Q$  seems reasonable because the communication pattern may be the same for all brands in a product category. In addition, the closed-form expression of the proposed model has some other advantages, especially it enables researchers to employ the NLS estimation procedure.

#### 4. APPLICATION: DIFFUSION OF ADSL SERVICE IN JAPAN

##### 4.1 The ADSL Market in Japan

According to the Japan Ministry's statistics, by the end of September 2002, the number of ADSL subscribers in Japan totaled about 4.22 million, adding about 1.8 million or an increase of 77.5 percent as of a-half-year before, at the end of March 2002<sup>1</sup>. This number breaks

down to 1.72 million subscribers of NTT East and NTT West, and 2.50 million subscribers of other service providers.

The ADSL market of Japan expanded rapidly with the entrance of large competitors. At the end of 1999, Tokyo Metallic Communications and eAccess began to launch internet connection service –ADSL for home users by offering data transfer speeds up to 640kbps. It cost subscribers more than 6,000 yen per month at that time. The ADSL market experienced slow-growth in the first year. But with the entry of NTT, the market began to take off. The ADSL had not been a viable choice for NTT, because NTT had decided to employ optical-fiber cables for access lines instead of copper-cable based technologies (ADSL). However, it would be projected to take more than ten years to complete the overall implementation. Therefore NTT decided to adopt ADSL during the construction of the optical-fiber networks. By the end of June 2001 when NTT had entered into the ADSL service market about half a year ahead of Yahoo!BB's new entry, the total number of cumulative subscribers increased up to 300 thousands. This number was about thirty times larger than that of a half-year before when NTT entered into the market. The market share of NTT was as high as 63 percent. In addition, not only the NTT, other companies such as Tokyo Metallic and eAccess also expanded their markets more rapidly than before.

With the entry of Yahoo!BB, the competition among companies became intense, especially in terms of price reduction. Before Yahoo!BB entered into the market, average monthly fees of the top-three companies (NTT, Tokyo Metallic Communications, and eAccess) were around 5,400 yen, which is approximately 20 percent reduction compared with that of the previous year. When Yahoo!BB offered monthly fee of 2,280 yen in August 2001, the large price reduction contributed to the rapid expansion of the market. The number of monthly subscribers increased from 110 thousands in July 2001 to 270 thousands in October 2001. Thereafter, the number of monthly subscribers remained around 330 thousands. From the beginning of 2002, the market share of NTT East and NTT West remained virtually unchanged about 40 percent. This means the market shares of NTT and the non-NTT camp were stabilized. However, the market shares among the non-NTT camp had been changed. According to the ministry's statistics, with the integration of Metallic Communications Corp. into the Softbank group, Yahoo!BB held about 21.6 percent of Japan's ADSL market. It appeared that Yahoo!BB and NTT began fierce competition for the top market share. With the development of ADSL technology, the maximum speed for data transmission has been changed from 640kbps to 26Mbps. Now, the difference of ADSL monthly fees among the companies is not large –from 3,500 to 4,000 yen. At present, the competition among companies is mainly based on service and quality but not price.

<sup>1</sup> To investigate the competition between the NTT group and the Others in the ADSL market, period from Jan. 2000 to Sep. 2002 is under consideration.

Figure 1 Monthly subscribers of ADSL in Japan

Figure 1 outlines the growth of monthly subscribers for the total market, the NTT group, and the Others. Since the data on the number of subscribers of each company could not be obtained easily, we used the data provided by the ministry's statistics to analyze the competitive relationship between the NTT group (the total of NTT East Corp. and NTT West Corp.) and the Others (the total of other companies) in this study.

#### 4.2 Methodology

At the time when the analysis was conducted, the ADSL market in Japan was at the growth stage finishing up the introduction stage. With the entrance of large players like NTT and Yahoo!BB, the market grew up rapidly. In the concept of the proposed model, three forces – the external communication, the internal communication of a particular brand, and the growth of the total market would influence the diffusion of the particular ADSL service in a social system. Though both the NTT group and the Others benefited from the growth of the total market, the magnitude of the influence might be different. The influence of the total market on NTT would be large, since it was a popular brand among the people. On the other hand, the growth of the total market and the cumulative knowledge about the ADSL service made people consider the ADSL providers in a reasonable way. That is, the service offered by each provider did not differ significantly. Hence, the Others also benefited on some extent from the growth of the total market.

From August 2001, when Yahoo!BB entered into the market and announced to provide a low monthly fees of only 2,280 yen, the market demonstrated the aspects of the growth stage. The intense competition brought rapid price reduction and market expansion. Since Yahoo!BB was thought to have the advanced technology as well as low priced and high quality service, it would make some change in the competitive structure of the market. In this period, the influence from the growth of the market on the adoption of NTT service was expected to be getting similar with that of the Others. The proposed model is used to analyze the competitive relationship of ADSL service in Japan. The closed-form solution of the proposed model was used for estimation. Since the

characteristics of the ADSL market varied largely before and after Yahoo!BB's entry into the market, a two-period estimation was executed.

#### 4.3 Empirical Results

Monthly cumulative data of ADSL subscribers for the NTT group and the Others were used for empirical analysis. The data were simultaneously fitted to the equation (7) ( $j=1, 2$ ), employing the NLS procedure. The market potentials, however, must be separately estimated before conducting the NLS procedure. Since the ADSL market in Japan changed greatly after Yahoo!BB had entered into the market, the market potentials were also assumed to be changed. Therefore two different market potentials corresponding to before/after the Yahoo!BB's entry should be estimated. Although recent applications of diffusion models reported better forecasting results by using exogenous sources of information such as market surveys, secondary sources, management judgments, or other analytical models (Gatignon et al., 1989, Mahajan and Sharma 1986), the estimation of the market potential could be derived directly from the diffusion time-series data. In detail, applying the original Bass model to the category data for each periods, the market potentials of the introduction stage and the growth stage were estimated as 0.75 million and 5.55 million, respectively. We also assumed that  $p$  the innovative influence for the NTT group equal to zero in the estimation step. This is somewhat similar to the method used by Krishnan, Bass, and Kumar (2000).

Table 1 Estimation results of diffusion parameters

diffusion parameters	introduction stage (2000.1-2001.7)	growth stage (2001.8-2002.9)
Q	.3510 (.0741)	.1092 (.0408)
$P_1$	.0000034 (.00000093)	.0140 (.0014)
$r_1$	.0997 (.0242)	.0448* (.0212)
$r_2$	.2115 (.0323)	.0502 (.0184)

\*: significant at 0.05; others: significant at 0.01

( ): standard error

The estimation results are represented in Table 1. All the estimates are significant at 0.01 level except the one with asterisk mark. The results showed that the diffusion patterns for the NTT group and the Others are different. As for the Others, the three forces – the external influence, the internal influence, and the influence from the market growth all have positive and significant effects on diffusion, though the external influence is very small. The diffusion of the ADSL subscribers of the NTT group is mainly determined by the internal influence and the growth of the total market. The results also suggest that the diffusion patterns differ between the introduction stage and the growth stage. In the introduction stage, the influence of the total market's

growth on NTT was twice as large as that of the Others. Since the internal influence for each provider group was assumed to be identical and the external influence is very small, the larger value of the parameter  $r_2$  means the rapid growth of the NTT group. In the growth stage, the difference of the influence of the total market's growth on the NTT group and the Others became small. This is probably contributed to the entry of Yahoo!BB as the principal member of the Others.

Using the estimated diffusion parameters, the estimated diffusion patterns are computed separately for the NTT group and the Others. Figures 2 and 3 represent the estimated and the actual diffusion patterns for the NTT group and the Others, respectively. Comparing the diffusion patterns of the estimated with the observed, it is obvious that the proposed brand-level diffusion model fits to the ADSL data in Japan very well.

Figure 2 Observed and estimated subscribers (Others)

Figure 3 Observed and estimated subscribers (NTT)

## 5. CONCLUSIONS AND MANAGERIAL IMPLICATIONS

This work would be the first attempt to capture the diffusion dynamics by the three forces – the external influence, the internal influence, and the influence from the growth of the total market. Since the Bass model (Bass, 1969) was introduced into the marketing literature, a number of researches about innovation diffusion used the external coefficient  $p$  and the internal coefficient  $q$  to describe and explain the difference of innovation diffusion patterns. Empirical results across

different products and markets revealed that the Bass model fitted to the innovation diffusion data very well. Undoubtedly, using parameters  $p$  and  $q$ , the Bass model can successfully capture the diffusion dynamics when a particular product category is under consideration. However, managers are much more interested in the adoption or growth process of a particular brand and the competitive relationship among brands in a product category. One of the advantages of the Bass model is that it depends on the communication pattern underlying the diffusion process – the external communication through mass media, and the internal communication with the early adopters of the product. When we consider the communication pattern for a particular brand in a product category, not only the mass media and the early adopters of a particular brand, but also the growth of the total market would influence the diffusion of that brand. For some products or services such as the cellular phone and the ADSL service, the primary advantages of adopting these products or services are not so much different depending on the competing providers. Therefore, the influence of the growth of the category on the growth of each brand may be large. In the case of other products such as cars, the market of which is characterized as a completely differentiated market, the success of the total market may only have little impact on the adoption of a particular brand.

The principal implication of this study is the consideration of the category growth effect on the adoption of a particular brand to describe the brand level diffusion process. In the concept of the proposed model, the influence of the category growth on each brand can be different, and captured by the value of the parameter  $r$ . The empirical analysis revealed that the category growth effect on each brand was different, and varied with the growth of the market. The later entry may have the advantages of facing a established market with familiarity with the innovation, confidence about the innovation, and preparation for its adoption. In this study, the entry of NTT made up the ADSL market category and several brands grew up in the market. This also happened when Yahoo!BB entered into the market by using low pricing strategy. The success of the NTT and Yahoo!BB in the ADSL service market implied that the timing of entry is very important. NTT entered into the market about one year after the leaders such as Tokyo Metallic Communication and eAccess entered into market, when the ADSL had obtained high recognition. Yahoo!BB entered into the market six months after the NTT, and expanded its market share through large price reduction.

Through assuming that the internal influence parameter of each brand in a product category is identical, the proposed model can be aggregated to the category Bass model. This assumption brings the advantage of the proposed model that it can be solved in a closed-form expression as a function of time  $t$  only. Researches about the brand level innovation diffusion have

employed discrete models to describe continuous phenomenon (Mahajan, Sharma, Buzzell 1993; Parker and Gatignon 1994; Givon, Mahajan, Muller 1997, Modis 1997). Although the discrete method make it possible to easily handle the problems and test various assumptions about the effect of competition among brands, it has fatal shortcoming of estimation biases and sometimes it cannot provide the information on the estimation errors. Using the closed-form solution of the proposed model, the estimates and their standard errors can be obtained directly.

## Neural Networks Based Integrated Evaluation Method for the Effectiveness of CRM

**Qingliang Meng, Qinghua Kong, Yuqi Han, Jie Chen**

School of Economic & Management, Nanjing University of Science and Technology, Nanjing 210094, China  
mengzhi007@sina.com

### ABSTRACT

Customer relationship management (CRM) has become one of the leading business strategies in the new economy. The effectiveness of CRM can be measured as a satisfaction level achieved by CRM activities. CRM has emerged as a major business strategy for e-business, but little research has been done in evaluating the effectiveness of CRM because of its complexity. In this paper, on the basis of building a CRM evaluation index system, we propose neural networks based integrated evaluation method for the effectiveness of CRM. It can simulate evaluation made by experts and avoid subjective mistakes. The results from the simulation are satisfied.

**Keywords:** customer relationship management, neural networks, integrated evaluation

### 1. INTRODUCTION

Transforming enterprises to become customer centric to get more revenue and profit is one of the hottest strategies in business today. This strategy is known as customer relationship management (CRM). As enterprises pursue CRM strategies, they become aware that the costs and benefits of CRM initiatives are significant, and they strive to grasp the financial impacts and economic factors that contribute to their success. For enterprises to achieve ROI (return on investment) from CRM, investments in the application domains and technologies of CRM should contribute tangible business benefits to the enterprise, as well as intangible benefits. The effectiveness of CRM can be measured as a satisfaction level achieved by CRM activities. As CRM has emerged as a major business strategy for e-business, evaluating its effectiveness is very important. However, little research has been conducted to evaluate CRM effectiveness. In the CRM world, increased emphasis is being placed on developing measures that are customer-centric and give managers a better idea of how their CRM policies and programs are working [1].

In this paper, we develop neural networks based integrated evaluation method for the effectiveness of CRM. Because artificial neural network (ANN) acts as a model of real world system or function. The model then stands for the system it represents, typically to predict or to control it. Among the various artificial neural networks presented so far, the multi-layer feed forward neural network is employed in this study. It is found that the ANN modeling is very effective and accurate.

### 2. CUSTOMER RELATIONSHIP MANAGEMENT

CRM can be defined as managerial efforts to manage business interactions with customers by combining business processes and technologies that seek to understand a company's customers. Companies are becoming increasingly aware of the many potential

benefits provided by CRM. Some potential benefits of CRM are as follows:

- (1) Increased customer retention and loyalty
- (2) Higher customer profitability
- (3) Creation value for the customer
- (4) Customization of products and services
- (5) Lower process, higher quality products and services

### 3. A FRAMEWORK FOR EVALUATING THE EFFECTIVENESS OF CRM

#### 3.1 The CRM process model

Because it is difficult to evaluate tangible returns on the resources expended to plan, develop, implement, and operate CRM, we have to measure the intangible nature of benefits such as customer loyalty, service quality, value enhancement, effectiveness of processes, innovation of operation, service improvement, competitiveness, trust, and efficiency. To evaluate the effectiveness of CRM, we need to build a evaluation framework, it must be a multi index system and it must can evaluate the whole CRM process. In figure1 we give the model of CRM process.

From figure1 we can see. First, a company accumulates a huge amount of customer information and creates a customer profile. Next, the company discovers large and hidden customer characteristics through data mining tools and techniques. As CRM has tremendous potential for collecting and storing customer preferences, CRM can make it possible to create new products and customize existing products in innovative ways. Second, the company integrates all relevant information on each customer across the enterprise in order to facilitate more effective planning, marketing and services. Identified customer knowledge helps to find customer needs when a company interacts with customer. As customer requirements and expectations are met, loyal customers are created. Customer value can be added by product and service customization, additional information provision,

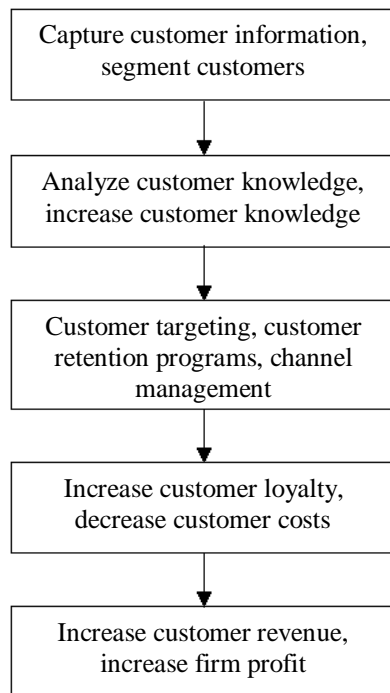

Figure 1. The model of CRM process

and quality enhancement. Understanding and collecting customer needs are critical to conducting these value-adding activities. Third, satisfactory long-term customer relationships can be established, as channels aid employees to serve customers effectively and profitably. Finally, the company increases revenues and profits. Typically, business value can be added by improving brand image, establishing customer relationships, enhancing public relations, and generating sales leads [2].

### 3.2 The evaluation index system for effectiveness of CRM

The model of CRM process can give a clue as to what perspective are important to evaluate the effectiveness of CRM. That is customer knowledge, customer interaction, customer value, and customer satisfaction. So an evaluation index system can be shown in figure 2.

Where, CK<sub>1</sub>: collecting appropriate customer information;  
 CK<sub>2</sub>: analyzing customer data;  
 CK<sub>3</sub>: acquiring new customers;  
 CK<sub>4</sub>: understanding customer needs;  
 CK<sub>5</sub>: improving skills of employee;  
 CK<sub>6</sub>: improve CRM techniques;  
 CK<sub>7</sub>: secure service;  
 CI<sub>1</sub>: appropriate response to customer request;  
 CI<sub>2</sub>: integration of business process;  
 CI<sub>3</sub>: improving channel management;  
 CI<sub>4</sub>: maximizing the effectiveness and efficiency of enterprise operations;  
 CI<sub>5</sub>: customizing products and services;  
 CV<sub>1</sub>: improving customer retention;  
 CV<sub>2</sub>: profits increase;  
 CV<sub>3</sub>: improving customer service and support;  
 CV<sub>4</sub>: building attractive virtual community;  
 CS<sub>1</sub>: improving service quality;  
 CS<sub>2</sub>: establishing relationship with customers;  
 CS<sub>3</sub>: responsiveness;  
 CS<sub>4</sub>: reliability.

The customer knowledge (CK) perspective represents the status of the customer segment and customer data management. Customer knowledge focuses on technology learning, understanding customer needs, and customer profiles, which influence ways of interacting with customers. The varied tastes and preferences of customers make it difficult to classify customers into a large homogenous population to develop marketing strategies. A customer wants to be served according to his or her individual and unique needs. To analyze customer needs, CRM uses appropriate data mining tools and data warehousing techniques. Technology learning is also important towards understanding customers. It is required, therefore, to assess employee skill to use customer information effectively. Security is another basic and critical prerequisite when dealing with customer information [2]. Security, in particular, has been a serious issue concerning online purchases and an impediment to the acceptance of the e-channel. Many customers are concerned about the amount of personal information that is contained in databases and how it is being used. Customers perceive safety of transactions and seller empathy as important.

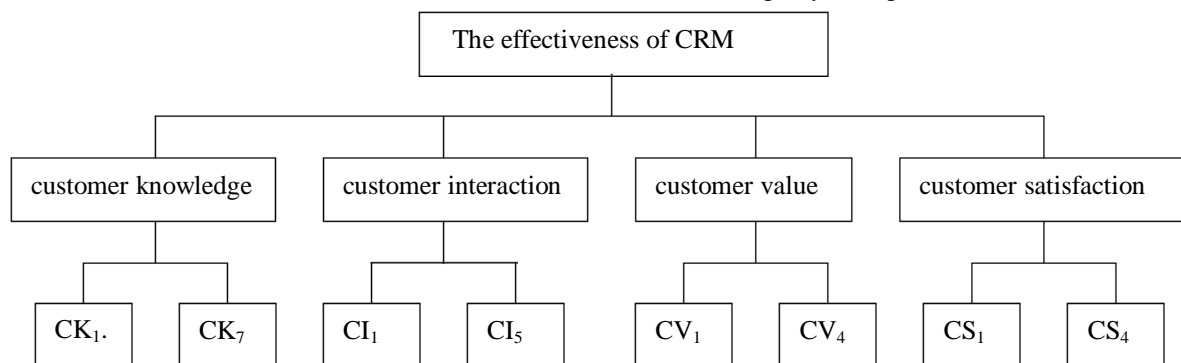

Figure 2. The evaluation index system for effectiveness of CRM

The customer interaction (CI) perspective represents operational excellence and channel management of customer services and management processes. To manage various communication channels efficiently, managers make an effort to monitor the business processes. Winer suggested a relational program that includes customer service, loyalty programs, customization, rewards programs, and community building [1]. To analyze customer interaction, some important measures need to be considered, such as the number of marketing campaigns, total cost for promotion, frequency of contents updates, payment, response channels, and so on. Communication channels not only include classic communication channels such as letters, fax, and telephone but also emerging new channels such as call centers, service centers, Web sites, and virtual internet communities. It is vital to manage various channels efficiently and immediately.

The customer value (CV) perspective represents the benefits gained from customers, such as lifetime value. If the customer is satisfied with the service of a company, there will be no problem concerning customer deviation. To maintain this relationship, the CV perspective continues to find ways to build customer commitment and loyalty. In addition, customers are identified by their value and are treated accordingly. Customer value describes tangible and intangible benefits gained from CRM activities, which help to arrange the relationship with the customer successfully. In order to determine the customer value, we need to analyze such information as customer retention, profits increase, customer service and support, virtual community. Current customer profitability should be calculated, establishing a baseline and comparing new calculations to that baseline periodically. Calculating customer value potential and using it as a guideline will be profitable in the future [3].

The customer satisfaction (CS) perspective represents the level of satisfaction achieved by products or services. Customer satisfaction is the feeling that a product or service meets customer expectations and determines whether the buyer will become a permanent customer or not. The assessment of customer satisfaction is one of the most important stages of the implemented model. Customer satisfaction is difficult to measure because it is hard to quantify the satisfaction level [4]. Customer satisfaction represents a modern approach for quality in enterprises and organizations, and serves the development of a truly customer-focused management and culture. Measuring customer satisfaction offers an immediate, meaningful, and objective feedback about customer preferences and expectations. Among the four perspectives, the customer satisfaction perspective is the most important because customer satisfaction is directly linked to a company's profits. Customer satisfaction can be measured from the four dimensions: service quality, the relationship between enterprises and customers, responsiveness, reliability. Responsiveness is the willingness to help customers and provide prompt

service [5]. Reliability is the ability to perform the promised service dependably and accurately.

#### 4. NEURAL NETWORKS BASED INTEGRATED EVALUATION METHOD

Artificial neural network algorithm has been used successfully in many applications, because it acts as a model of real world system or function. The model then stands for the system it represents, typically to predict or to control it. ANN can model a function even if the equation describing it is unknown the only prerequisite is representative sample of the function behavior and that is from the experimental data and not from a theoretical understanding. Figure 3 shows the schematic diagram of a multi-layer feed forward network used in this paper. The neurons in the network can be divided into three layers: input layer, output layer and hidden layers.

Figure 3. The structure of a multi-layer neural network

Each neuron of the output layer receives a signal from inputs through hidden layer neurons along connections with modifiable weights. The neural network can identify input pattern vectors, once the connection weights are adjusted by means of the learning process. The back propagation learning algorithm which is a generalization of Windrow-Hoff error correction rule is the most popular method in training the ANN and is employed in this work[6]. This learning algorithm is not presented here.

Scaling of the input-output data has a significant influence on the convergence property and also on the accuracy of the learning process. It is obvious that the range of the output of the network must be within  $[0, 1]$ . The input variables should be kept small in order to avoid saturation effect caused by the sigmoid function. Thus, the input-output data must be normalized before the initiation of training of the neural network. After the normalization, the input variables can then be easily made to fall in the range  $[-1, 1]$ . Further, the range of the normalized output vector component is made to fall within  $[0, 1]$ .

There are 20 indexes in the evaluation index system. But each index should have a score made by experts. The scores can be divided into five scales: 1, 0.7, 0.5, 0.3, and 0.1. Echoes best, better, medium, worse and worst respectively. In this example, we take the scores made by experts as the inputs ( $ck_1, ck_2 \dots cs_4$ ) of the neural network model. The expected output is only one neuron,

Table 1. The evaluation data made by experts

order	CK1	CK2	CK3	CK4	CK5	CK6	CK7	CI1	CI2	CI3	CI4	CI5	CV1	CV2	CV3	CV4	CS1	CS2	CS3	CS4	score

11	0.7	0.5	1	0.7	0.7	0.5	0.7	0.7	0.5	0.7	0.7	0.5	0.7	0.7	0.7	0.5	0.7	0.7	1	0.5	0.647
12	0.7	0.7	0.5	0.7	0.7	0.5	1	0.7	1	0.7	0.7	1	1	0.7	0.7	0.7	1	0.7	0.7	0.1	0.727
13	0.7	0.7	1	0.5	0.3	0.5	0.3	0.5	0.5	0.5	0.7	0.5	0.3	0.5	0.7	0.5	0.7	0.3	0.3	0.5	0.460
14	0.7	1	0.3	1	0.7	1	1	0.7	1	1	0.7	1	0.7	0.7	0.7	0.7	0.7	0.7	1	0.5	0.817
15	0.7	0.7	0.5	1	0.7	1	1	0.7	1	1	0.7	1	1	0.7	0.7	0.7	0.7	0.7	0.7	0.5	0.766

and it must be within  $[0,1]$ , and it represents the result of the evaluation. The result scales can be divided into four levels: if the value is between 0.7 and 1, we treat it as good, if the value is between 0.5 and 0.7, we treat it as medium, if the value is between 0.3 and 0.5, we treat it as poor, if the value is below 0.3, we treat it as very poor. In next section, we will develop a simulation from an example.

## 5. SIMULATION AND RESULTS

In this paper, we will use the data acquired from 15 firms, it is shown in table 1. The scores of each index were made by experts. The scores of last column are the results achieved by experts using multicriteria integrated evaluation method. We can use neural networks based integrated evaluation method to simulate. In this example, we choose the former 12 samples as training signals, and the left 3 samples as test signals. Then we use Matlab as the tool, leading rate is 0.0001, the number of hidden neurons is 7, the training times is 1500, weight adjusted parameters is 0.5. The results can be obtained in table 2.

Table 2. The learning results

Order	Results of training	Expected outputs	Errors / %
1	0.8583	0.861	0.270
2	0.6008	0.604	0.320
3	0.3394	0.340	0.060
4	0.4726	0.488	1.540
5	0.7078	0.713	0.520
6	0.9274	0.931	0.360
7	0.8057	0.810	0.430
8	0.6420	0.641	-0.100
9	0.6739	0.683	0.910
10	0.8253	0.827	0.170
11	0.6413	0.647	0.570
12	0.7257	0.727	0.130

We can see it is very similar to the expected outputs. The test results are shown in table 3. The error variation curve is shown in figure 4. The results of evaluation are consistent with the scores made by experts. Thus, the simulation is satisfied.

Table 3. The test results and Categorization

order	1	2	3
Test results	0.4508	0.8366	0.6615
Results from experts	0.4600	0.8170	0.6300
Errors / %	1.68	2.37	4.74
Categorized by simulation	Poor	Good	Medium
Categorized by experts	Poor	Good	Medium

Figure 4. The error variation curve

## 6. CONCLUSIONS

Customer relationship management is one of the leading competitive business strategies in the new economy. It is very important to evaluate the effectiveness of CRM, because it is beneficial for enterprises to carry out the CRM activities. In this paper, on the basis of building a model of CRM process, we set up a evaluation index system for the effectiveness of CRM, then neural networks based integrated evaluation method are proposed, and the results of the simulation are satisfied.

That is to say, the evaluation method is a powerful assessment tool to evaluate the effectiveness of CRM. We expect that this related work of the method should be further researched so that we can evaluate other fields.

### ABSTRACT

This paper argues that there are four key conceptual techniques used in Customer Relationship Management (CRM) which should be considered Imperatives for contemporary 21st century e-Business today. Customer Relationship Management itself may be defined as an attempt to find the most efficient way to focus the Marketing effort in order to generate revenue. The antecedents of successful Customer Relationship Management techniques may be found in 20th Century and even 19th Century traditional Direct Marketing constructs. Years of data from this sub-discipline of Marketing, data analysis, and testing confirm the efficacy of these key techniques. Customer Relationship Management concepts which are examined as Imperatives for 21st century e-Business are: 1) Customer Lifetime Value (LTV); 2) Customer Acquisition Cost (CAC); 3) Split-Run (A/B) Testing; and 4) Recency, Frequency, and Monetary Value (RFM) Analysis.

**Keywords:** e-business, Customer Relationship Management, CRM, Lifetime Value, LTV, CAC, A/B Split Testing, RFM analysis

### 1. INTRODUCTION

This paper explores the Nineteenth and Twentieth Century antecedents of modern Customer Relationship Management in an attempt to see how they can contribute to greater 21<sup>st</sup> century e-business profitability.

From a theoretical point of view, Customer Relationship Management (CRM) can be seen as a more efficient focus of the effort to generate revenue—the task of Marketing. The reason that Customer Relationship Management has been gaining prominence in today's economy is that it has demonstrated success at generating revenue more efficiently. [1]

The current practice of Customer Relations Management today confirms the prescience of Peter Drucker when he wrote in 1973:

To know what a business is we have to start with its purpose. Its purpose must lie outside of the business itself. In fact, it must lie in society since business enterprise is an organ of society. There is only one valid definition of business purpose: to create a customer. [2]

The foundation of CRM success today is the concept of Customer Lifetime Value (LTV). Lifetime Value may be thought of as an elaborate extension of Pareto's principle.[3] (Pareto's maxim that eighty percent of an organization's revenues will be generated by twenty percent of its customers has been well accepted for decades.)

### 2. ANTECEDENTS

However, Lifetime Value is but one of a series of concepts whose success has been proven and refined by a sub-discipline of marketing called Direct Marketing. In 1872, American merchant, Montgomery Ward, and later, Richard Sears sent their catalogs to a predominantly rural population (9 out of every 10 Americans lived on farms) who were unable to visit a retail store. [4] Since that time the field of Direct Marketing has developed a number of operational concepts that have grown in sophistication, power, and profitability through a range of media including catalogues, direct mail, telemarketing, and direct response advertising.

The Direct Marketing concepts which have the most to offer to today's e-commerce practitioners are the ones identified as imperatives in this paper.

The success and wisdom of Direct Marketing has been earned over the better part of a century. The principle reason is that Direct Marketing also known as Database Marketing, enjoys such success is its 100% accountability. In contrast to mass media promotion, Direct Marketing identifies exactly whom it wishes to target (individuals by actual name). This allows collection of data on exactly who responded yielding 100% accountability across a range of metrics. For example, if 100 catalogues are mailed to 100 names, the direct marketer knows the names of the 10 who responded and exactly what they bought and exactly how much each sale cost.

In addition to Lifetime Value (LTV) other operational concepts which Direct Marketing has developed and implemented over the years include Customer Acquisition Cost (CAC); Split-Run Testing (A/B); and

Recency, Frequency and Monetary Value Analysis (RFM). Each of these constructs can be adopted for use by e-business. Since all the techniques can be implemented and analyzed quantitatively, they can easily be applied across language and culture making them ideal for global application.

Because these antecedents have been so reliable and successful in the past for Direct Marketing, their promise for modern e-Business is obvious. Once fully appreciated, these Direct Marketing antecedents may be regarded as 21<sup>st</sup> century Customer Relationship Management (CRM) Imperatives.

### 3. IMPERATIVES

The first of four antecedents of the practice of Customer Relationship Management (CRM) which should be regarded as imperatives is the concept of Lifetime Value. This term posits that there is a lifecycle to the relationship that customers have with an organization or business. During the period of the relationship between the beginning and the end, the company has an opportunity to lengthen or shorten the relationship based on how it “manages” the relationship. “Manages” is an unfortunate choice of words since it indicates an almost adversarial nature of the relationship, or at the least, an unequal one, between the manager and those managed. Nevertheless, Customer Relationship Management is the term in accepted use today.

#### 3.1 LifeTime Value (LTV)

Enlightened businesses realize that every time a customer has an interaction with the company (or “touch” in CRM language), the relationship can be either be deepened or weakened. If the interaction is a positive “touch,” there is an opportunity for cross-selling and increased profit. An additional benefit of deepening trust and frequency is loyalty. Loyalty extends the term of the relationship so that a customer who has been with a company five years continues for six, eight, or ten years. This extension not only increases the net present value (NPV) of the projected revenue stream, but does so at lower cost. This in turn, increases margins and leads to greater profitability. [5]

Any calculation of Life Time Value (LTV) must take three factors into consideration:

1. Margin
2. Retention Rate
3. Discount Rate

First, Margin is the annual revenue that customers generate minus the company’s operating expenses in serving them. Second, the Retention Rate is the percentage of first-year customers who can be expected to continue into the second, third or n year. And third, the Discount Rate is the current cost of capital. [6]

LTV tracks the buying behavior of a group of customers and projects it into future years. In order to compute LTV, we need to know the following: [7]

- number of customers acquired in first year of business
- cost of promotional materials needed to acquire them
- cost of promotional materials after their first purchase
- retention rate (first year customers who continue into second year)
- average order size
- number of orders per year
- cost of goods sold
- average rate of returns, exchange, and damages
- market rate of interest

The Imperative is that once Lifetime Value has been computed for each customer, an analysis can be made to identify those *customers who represent greater value to a company’s future* and those who represent less. Decisions can then be made as to which customers are the company’s best prospects, which are marginal and which are unprofitable to the company. This analysis helps decision-makers formulate promotional strategies which can most efficiently grow a company’s profitability. Managers can now make informed decisions as to whether to concentrate on customer retention, acquisition, or win-back. [8]

#### 3.2 Customer Acquisition Cost (CAC)

The next antecedent that is integral to implementation of Customer Life Time Value (LTV) is the accurate determination of Customer Acquisition Cost (CAC).

Reichheld claims that “On average, U.S. corporations tend to lose half their customers in five years, half their employees in four, and half their investors in less than one.”[9] The implication of these facts, underscores the continuing requirement for companies to replenish their customers. The cost of new customers is seldom free. However, not all customers cost the same to acquire. Nor do acquisition programs always yield the same quality customers. Moreover, customer acquisition costs can vary wildly.

Calculating Customer Acquisition Cost is a technique that can assign a dollar cost to acquiring or re-acquiring each customer, old or new. A Customer Acquisition Cost ratio is used to help determine whether to retain an existing customer or to acquire a new one.

In hindsight, it can be seen that among the many factors responsible for the dot.com bust was lack of appreciation of CAC. At the height of the dot.com boom, to give just one example, the company, e-Toys, was reportedly spending more than \$700 to acquire each new customer. Unfortunately, each new customer’s LTV was only \$87. The inevitable result was that for

every new customer acquired, e-Toys would absorb a loss of over \$600.

To truly appreciate the value of keeping track of CAC, there is one informative general Direct Marketing principle to apply. The rule-of-thumb used by direct marketers is that it costs between 5 to 10 times more money to acquire a new customer than it costs to retain a current customer. [10]

Of particular importance is the fact that the Customer Acquisition Cost (CAC) for pure-play Internet retailers is higher than their multi-channel counterparts. Internet retailers are defined as those with physical stores or mail-order catalogs in addition to their web sites. [11]. CAC is defined as total sales and marketing expenses divided by new customers accounts. Author Morrison predicts that average Customer Acquisition Cost will rise to \$150 for web-based retailers vs. \$95 for multi-channel retailers in 2004.

One of the most difficult problems associated with computing true CAC is that it becomes difficult to distinguish between which sales and marketing programs stimulate repeat sales to existing customers and which result in new customer acquisition.

The Acroterion Company, estimates that CAC for pure-play retailers is \$82 per customer while a multi-channel retailer's is only \$31 per customer according to a survey of 221 retailers conducted by Shop.org. [12]

Compared to a multi-channel retailer, the pure-play retailer has a much more difficult task in identifying and reaching potential customers. While direct marketers can choose from more than 1,000,000 databases of names and addresses of groups segmented by demographic, geographic, and psychographic variables, the pure-play retailer has a much more difficult job. The fact is there are so many fewer lists available containing valid e-mail addresses. In this day of rampant "spam" and extraordinary privacy concerns, direct solicitation of potential customers via email no longer appears viable. Consequently, pure-play retailers must resort to more expensive methods like on-line advertising and search-engine listings.

### 3.3 Spit-Run (A/B) Testing

The next antecedent is key to Direct Marketing's success, the concept of Testing. Direct Marketers test every variable they can in an effort to achieve optimization in their choice of merchandise, their value proposition, and the elements of their promotional materials.

E-Commerce practitioners have much to learn in this area. First, there is the scope of what to test – everything that is important. And, second, there is the relentless

dedication to testing, the never-ending emphasis on optimization.

One of the most frequent statistics mentioned about e-commerce shopping is that 7 out of every 10 shopping attempts on line are abandoned. Clearly, this is unacceptable. It is an area ripe for improvement. It is here that ingenious testing can make a significant contribution.

The term that direct marketers use to describe their testing technique is Split-Run (A/B) Testing. On the Internet, it can be used to test such things as product features, web page design, and navigation, value. [13]

In its simplest form, the e-commerce retailer selects one--and only one--variable at a time to be tested, such as the number of steps necessary for a successful shopping cart check-out. Assume that seven is the current number of steps, called the "control." A new 6-step sequence is now constructed. Then, a method is developed so that every other visitor to the shopping site will be offered the 7-step checkout and every other visitor will get the new 6-step sequence.

By tracking how many shoppers have used the 6-step vs. how many have used the 7-step sequence, we can determine whether reducing the number of steps has any significant effect on the outcome. If the new 6-step sequence increased the number of users, then it "wins" the test and becomes the new "control" and the 7-step sequence is retired.

The imperative here is that e-commerce retailers must constantly search for variables to test and be relentless in their commitment to continual testing. Moreover, they must commit to a continual refinement of all aspects of marketing program in keeping with those test results.

The Internet offers the extraordinary opportunity for dynamic, real-time testing that traditional direct marketers can only dream about. For example, in a 24-hour period, an e-commerce retailer can vary the size of a picture of an item offered on a web page whereas a traditional direct marketer using a picture on a page in a printed catalog would only be able to compare results from the control, the current size, Size A, and the new size picture, size B. And then the retailer would have to wait to reprint the catalog in order to test again.

### 3.4 Recency, Frequency, Monetary Value Analysis

The final antecedent is called RFM analysis which means analysis of the Recency, Frequency, and Monetary Value of customer purchases.

RFM analysis is a refinement of Pareto's principle, commonly known as the 80/20 principle, which

translates into marketing operations as the axiom that 80% of an organizations revenues will be generated by 20% of its customers.

Recency, Frequency, and Monetary Value (RFM) Analysis predicts customer behavior. [14] Attention to RFM delivers empirical proof of a company's best customers. Moreover, it predicts exactly which promotional solicitations will be most successful by market segment. Each record of an existing database is coded to identify which customers bought most recently, which customers bought most frequently, and which customers spent the most money on the company's goods and services.

At first, RFM analysis appears counterintuitive, because it is based on the principle that customers who bought most recently will be the most likely to buy again. However, the proof of this has been demonstrated empirically time and again by Direct Marketers. Likewise, the principles of frequency of purchase and dollar amount spent have also been demonstrated to be empirically sound. Marketers code all customers into RFM cells and examine the response rates of customers in each cell when exposed to the same promotion. Generally, Recency is weighted at 50%, Frequency at 30%, and Monetary Value at 20%. [15] Chi square analysis is used to analyze the data and produce results.

### 3.4.1 Migration Analysis

A refinement of RFM analysis is called Migration Analysis. Results of migration analysis indicate patterns of customer migration, which allow the user to predict which cells customers will migrate to in the future. This, in turn, will permit the company to focus promotional efforts against the most likely and receptive segment cells. Conversely, those customers (cells) that will be most likely to migrate into lower ranking cells can similarly be predicted. [16]

The imperative here is that RFM analysis is based on data that is readily available to e-Businesses. Knowing the usefulness of such data is ample incentive to gather it consistently. Once RFM analysis becomes a central part of the Customer Relationship Management process, it can become a powerful tool which e-Businesses can implement to increase their profitability.

## 4. CONCLUSION

Finally, as modern, traditional marketing emerged during the second half of the 20th century, its emphasis was on mass distribution and mass media promotion. This type of marketing largely ignored the valuable lessons of one-to-one marketing that its earlier sub-discipline, Direct Marketing, had learned and refined.

Today, there has been an explosion of one-to-one marketing opportunities thanks to the World Wide Web, making the tried and tested lessons of Direct Marketing imperative for any e-business to study. The reason is simply that the business model closest to successful 21<sup>st</sup> century e-business is not traditional 20<sup>th</sup> century "modern" marketing, but venerable Direct Marketing. It is this body of experience that holds the greatest promise for creating a sustainable competitive advantage and greater profitability for e-Business.

# Supporting Small Businesses' Penetration of New International Markets - Practitioner's Approach.

Jaroslav Jandos

Faculty of Informatics and Statistics, University of Economics, Prague 130 67, Czech Republic  
jandos@vse.cz

## ABSTRACT

Small businesses typically have limitations in areas of modern marketing and the use of ICT and I-commerce (Internet-commerce) in particular for penetration of new (mainly international) markets. An approach that can be used to address these limitations – i.e. method and implementation concepts based on the use of external consulting team (including University students) – is presented in this paper. Our approach is practically oriented and has attractiveness for small businesses in that it typically can provide practical results in relatively short time (several months) with reasonable costs. Practical usefulness of this approach, which is also an example of University–Industry partnership, is illustrated by implementation of method in a small Czech business.

**Keywords:** I-marketing, small business, SME, 1:1 marketing, CSF

## 1. INTRODUCTION

Small businesses often aim at penetration of new, often international, markets. For this purpose not only traditional means and ways (methods) but also means of ICT (Information and Communication Technologies) and corresponding methods are used. Small businesses often don't have own employees with required qualification – especially in areas of marketing, ICT (including Internet) etc. This is the main reason why above mentioned activities of small businesses are often executed with assistance of external consulting team. These services are often expensive and project often lasts long. For these reasons it seems reasonable to support these small businesses activities by consulting team, which includes University students. They often have reasonable qualification and can join project for fraction of costs of professional consultants.

“Small business” includes not only SME (Small and Medium Enterprise -classification of which can be different in different countries) but also other enterprises, which can find presented approach as valuable.

Although our approach is not limited to small businesses it has a special attractiveness for them in that it typically can provide practical results in relatively short time (several months) with reasonable costs.

Paper is oriented towards support of small business's expansion to new (mainly international) markets using ICT, namely Internet and Internet marketing and Internet commerce.

This support was executed as project with specified duration, resources and goals. Project was executed in small business using consulting team (including University students) with following main goals

- development of method for finding new (mainly international) markets for small business's penetration, resulting in new contracts
- demonstrate to small businesses the advantage if ICT's (mainly Internet-based) use in internal and external commercial activities
- training of small business's employees in novel approaches and use of ICT in such a way, that they can use these means further even after conclusion of the project

Paper topics include namely

- development of simple practical method for support of small business's penetration of new markets and it's practical execution as project
- University - Industry partnership, by inclusion of University students into consulting team
- knowledge transfer between members of consulting team and small business's employees during the Project

## 2. ROLE OF CONSULTING TEAM

The method (see below) is based on use of consulting team consisting typically of experienced professional (acting as project manager) and 3 to 4 university students

- consulting team is group of external experts, who execute those activities for which small business does not have own qualified employees. These are especially areas of marketing, e-commerce, use of ICT in business, project management.
- from the point of view of perspective customers/partners consulting team works fully “in the background” i.e. all external commercial activities are carried out by small business
- consulting team members can be permanently located in different geographical localities (in one country, even in different countries). They collaborate on reaching the objectives and deliverables of methodology for small business. Based on project plan they participate in

specified activities (submission of deliverables to small business's approval etc.) with small business management. For these reasons the use of convenient methods and technologies for collaboration is important.

Consulting team completes the following tasks

- manages individual steps of method, which are implemented as processes, proposed and managed by consultant. At the same time, the current small business processes are executed, i.e. project processes are mapped "on top" of current processes. After project termination small business can decide to adapt some of these project processes as his new processes, which are now executed by small business's own employees. Small business appoints own employees (typically with limited qualification) for execution of particular project steps
- proposes structure and the way of project management, project goal, expected project resources. After approval by small business this is the basis of the project
- proposes partial methods and approaches used in individual steps of project, ICT used in project as well as methods of communication and collaboration in project
- for particular tools/methods used in project (e.g. Internet market research using search engines, collaboration technology) provides training of small business employees (at least of those who take part in project) so that after project termination they can use these tools by their own.
- provides (with small business's assistance) actual execution of those activities for which small business does not have own qualified employees

### 3. METHOD – BASICS

For formulation of method for supporting small business expansion to new international markets mainly the following factors are taken into account

- method is based on known concepts of marketing, I-marketing, ([1], [2], [4], [8]) e-commerce, I-commerce ([5], [6], [9]). These concepts are applied in such a way that concrete benefits for small business are reached within reasonable time (several months) and with reasonable costs. Approach to method formulation is not governed by full-width theoretical approach but more by an attempt to formulate relatively straightforward method, which could be implemented relatively quickly under conditions, which are typical for most small businesses. The core of the method is the discipline of Internet marketing.
- it is assumed that small business typically does not have own employees with required qualification in areas like ICT, marketing, I-commerce. This is (on the basis of our practical experience) particularly true for smaller businesses. Therefore the implementation of method with the use of external consulting team is typical. In case small business has own qualified employees it can implement method by its own staff.

- Implementation of method is considered to be a project, with all required attributes. Project is typically managed by head of consulting team. Project team includes consulting team members as well as small business's employees

#### 3.1 Marketing – Basic Approach

Typical marketing activities are executed as steps of the method. However specific approaches have been selected for their implementation. These are namely the following

- Internet advertising (banners, search engine marketing etc.) was not used at all. Only active approach to market analysis was adopted. ICT based methods were primarily used – heavy use of Internet for analysis of company web sites, B2B info portals, e-marketplaces (as source of info) as well as search engine use – supported by traditional methods – analysis of printed materials acquired by project team, phone contacts etc. Info on particular potential business partner ("lead") was made more accurate until the responsible person was found, who was then contacted
- For ethical reasons the responsible person at potential partner was typically first contacted by short phone call in order to find out whether he/she agrees with product info being sent to him/her (i.e. "permission-based promotion")
- Marketing info including product info was delivered to potential partners typically by e-mail, company web site (only very basic info – this web site was operational before start of the project) or by 1:1 presentation in separate rooms of Quickplace (for potential partners with the greatest "value" – see below) which was (in step 6 of the method) further made more accurate so that it reacts to the exact requirements of particular partner

In the course of marketing activities several strategic decisions has to be made:

- Mass marketing versus direct marketing  
Approach of direct marketing was adopted in which only the selected potential partners (included in marketing database – see below) were contacted
- OEM versus brand marketing  
Depending on the characteristics of target market as well as on type of potential partner (i.e. wholesale – distributor or integrator) combination of OEM and brand marketing and sales was used on all markets, with OEM having greater success.

#### Marketing database

Specific marketing database tool was designed and developed as part of the method [3]. It includes up-to-date and relevant marketing meta-information on analyzed markets. This information includes among others – information content, info available on-line or off-line, business subject concerned (customer, competitor, distributor, integrator,...), market segment (i.e. small business's product concerned), region and country, format of primary info (catalogue, on-line

catalogue, corporate web-site,...), importance, contributor (into database).

In the project it's content is updated continuously by members of project team. It is used mainly in steps 5 and 6 of the method by all participants of the project. It was developed in Linux/Apache/PHP/MySQL environment as Web application and made accessible by URL from Quickplace.

### 3.2 Collaboration Technology

Innovative use of collaboration technology stems from the fact that it is used not only for collaboration but also (and to significant degree) for marketing purposes (see below)

Geographical distribution of project participants (small business, members of consulting team, potential customers) has led to use of collaboration technology. This distribution as well as requirement of asynchronous ("anytime") communication have resulted in the requirement for technology from "different time – different place" quadrant of collaboration technology classification [7]. Lotus Quickplace – Team Workplace, which belongs to category of "web-based team/project rooms" was selected.

Quickplace, implemented in client/serve architecture, requires only Web browser as client, has simple user interface, which makes it very easy to use even by non-specialists. It is based on specification of different "rooms", which can be used by different (groups of) users. Browser-based client/server architecture makes it very convenient also for inter-organizational collaboration.

In pilot project Quickplace was used mainly for

- communication and collaboration inside consulting team as well as for collaboration "consulting team – small business"
  - o collaboration on preparation and approval of deliverables of project (reports, lists, Web presentations)
  - o project management – activity plans, tasks monitoring, calendars etc.
  - o knowledge repository (e.g. marketing database)
  - o (simple) workflow
  - o automatic notification of users by e-mail under defined conditions (e.g. weekly summary "what is new", new task)
  - o use of URL for access to other Internet resources (e.g. to project marketing database developed as Internet client/server system from this environment).
- marketing purposes - communication with potential customers
  - o specifically for 1:1 marketing (personalized Web presentations for limited number of potential customers in step 5 of the method)

Quickplace server was used as service - in ASP

(Application Service Provider) mode. This has led to very short "lead time" of using it in project, as no installation and very limited administration activities were required. Quickplace's use in pilot project has led to considerable savings in project costs.

## 4. METHOD – DESCRIPTION

Method consists of the following 6 steps

- Step 1 - Introduction. Small business's analysis, Project – Start - up
- Step 2 - Business model documentation
- Step 3 - Selection of new (potential) markets
- Step 4 - Market research
- Step 5 - Internet marketing plan development
- Step 6 - Sale supported by ICT and I-commerce

**Step 1** Introduction. Small business's analysis, Project – Start - up

Objectives

Main objective of this step is execution of small business analysis including firm description, organizational structure, financial situation, preparation of report on current firm situation, preparation of SWOT (Strengths Weaknesses Opportunities and Threads) analysis.

Second objective is mutual acquaintance of consulting team with people from small business. Consulting team introduces to small business concept of this method. Project manager (typically head of consulting team) presents to small business management the basic project plan (steps, dates, resources, deadlines) Project team members from both sides are appointed.

Key deliverables:

- document "description of the firm"
- document "SWOT analysis"
- document "project management and project team"

All deliverables (in all steps) must be approved by small business management. Decisions included in these deliverables are then interpreted as small business's management decisions taken on recommendation of consulting team.

Steps (Tasks):

- visit of consulting team to small business premises
- analysis of internal firm documents by consulting team
- interview of consulting team with management of small business (mainly in the areas of organization, production, sales, marketing)

**Step 2** Business model documentation

Objectives

Main objective of this step is mapping and documentation of current "business model" mainly on the basis of internal company information, which can be – if the need be – extended from external sources. Consulting team acquires this information from small

business employees (mainly from sales and marketing) and eventually from company's ERP system, if available. Business model includes

- current products (properties, comparison with competition)
- production capacities (evaluation, possibility of expansion)
- current markets (description, CSF (Critical Success Factors))
- current distribution channels (partners, conditions, way of price specification, profit creation)
- current customers (products, volumes of sale, price specifications, customers requirements, customers satisfaction)
- specification of "core business" i.e. the main activity of the small business, which produces profit

Key deliverables:

- documents "products", "production capacities", "current markets", "currents distribution channels", "current customers". Some of these documents may already exist, some even in database form.

Steps (Tasks):

- analysis of firm's internal materials/documents by consulting team (see above)

### Step 3 Selection of new (potential) markets

Objectives

Main objective of this step is preparation of list of several new potential markets (or their segments), which will be analyzed in greater detail in next step. List contains the basic attributes of markets (advantages/disadvantages for small business, entry barriers etc.) List should contain the markets, on which – according to current information from steps 1 and 2 – the small business could have a chance of success (i.e. realization of sale), i.e. such a markets for which there are no known barriers for small business's penetration of the market (product quality, prices, after sale service, market requirements etc.)

Key deliverables:

- list of new potential markets (including their basic characteristics)
- ev. basic vocabulary (terminology for foreign markets)

Steps (Tasks):

- searching in information sources (Internet, other digital sources – databases, traditional sources) in order to find new markets
- basic analysis of potential new markets (from the point of view of small business's penetration)
- small business management approves the markets recommended by consulting team

### Step 4 Market research

Objectives

The main objective of this step is preparation of

cost-acceptable analysis of selected markets, taking into account that the result need not be as complex as results from much more expensive specialized marketing firms or from international marketing databases oriented towards area of specialization. Analysis contains information on markets and is used in the following steps of method.

Key deliverables:

- for each analyzed market
  - o market functionality (rules, entry requirements)
  - o geographic location (language, culture)
  - o volume (in prices)
  - o distribution channels (structure/model, most important players – leads)
  - o specification of prices
  - o market and channels participants
  - o potential partners, customers
  - o influencers
  - o competition
- marketing database including up-to-date and relevant marketing information on analyzed markets. It's content is updated continuously. It is used mainly in steps 5 and 6.

Steps (Tasks):

- analysis of individual markets (executed by consulting team with assistance of small business employees), using Internet resources and ICT with the goal of creation of marketing database

### Step 5 Internet marketing plan development

Objectives

Planning of marketing activities, which will lead to interest in buying small business's products from new subjects in new markets. These subjects were identified in previous step. Although even the "traditional media" (phone, fax, print etc.) are used for these marketing activities, the emphasis of this step is on the use of ICT – namely Internet and Internet marketing.

"1:1" or "1:many" marketing as well as different ICT technologies can be proposed in the plan - E-mail, promotion on Internet sites, participation in vertical e-marketplaces, product presentation on Web-site etc.

Key deliverables:

- marketing plan

Steps (Tasks):

- preparation of marketing plan, which includes subjects of interest to small business as well as specification by which marketing approach they should be contacted

### Step 6 Sale supported by ICT and I-commerce

1<sup>st</sup> sub-step

Objectives

Execution of marketing plan prepared in previous step (communication, providing potential customers the marketing/product information needed), which result in

expression of interest from these subjects.

#### Key deliverables

- marketing plan's execution

Final "deliverable" of this sub-step is expression of interest of potential buyers, providing them the required info on small business's products.

#### 2<sup>nd</sup> sub-step

Main objective is to execute, especially by use of ICT and I-commerce, the remaining steps of commerce transaction – i.e. negotiation of contract (including price), delivery, payment, customer after-sales support. Small business uses also traditional means in these steps. But this sub-step puts emphasis on the use of ICT and I-commerce to supplement these traditional channels. However ICT and/or I-commerce can be used only if accepted by potential customer.

#### Key deliverables:

- execution of complete commerce transactions i.e. realization of sales (with potential customers), as it is also the main aim of all activities (both in methodology and in project)

#### Steps (Tasks):

- specification of means of ICT and I-commerce, which will be used for full execution of individual commerce transactions "partially" executed in 1<sup>st</sup> sub-step, with regard to specific conditions of each transaction.

As often negotiation of contract can take longer time (e.g. several months) the "final point" of this step in this project was set approximately to the start of two-side negotiation of contract on basis of information gathered during the project. Remaining activities were executed mainly by small business. If the need be, small business can use help of other subjects (lawyers etc) during the final stages of contract negotiations.

## 5. PROJECT

For project a production firm was selected, with about 400 employees, 3 product lines, limited marketing qualification, very basic brochureware Web-site.

Consulting team included 5 members. Project manager (located outside the country), 4 masters students (in different locations in the country) working on project part-time. They were oriented basically at - ICT (1), marketing (2), training (1). Project duration approximately 6 months.

Consulting team's activities - project management (including provision of professional Project Manager) and use of collaboration technology (Lotus Quickplace) were fully covered by IBM Software Group.

In Step 1 and 2 SWOT analysis was performed. Because of 3 different product lines, separate SWOT analysis

was executed for each product line. Project team was set-up for each product line, including 1 consultant and 2 small business employees. Quickplace was introduced and used heavily for communication and collaboration during the project, both inside consulting team as well as in "consultant – small business" area. Project organization, time-scale etc. was also set-up in Step 1.

In Step 3 - two or three new international markets were selected, based on consultant's recommendation, for each product line. Orientation towards international markets is important decision, as it influences many following activities, resulting in greater demands (on consultant, resources, costs, information etc.) than sole orientation to home markets.

In Step 4 several approaches have been used including Internet search engines, analysis of e-marketplaces. Between 20 and 70 potential new partners were located for each product line on markets selected in previous steps. Global marketing database Kompass was used on very limited scale, giving less than 10 contacts (for 2 Euro/profile).

Specific marketing database tool was developed in this step and used heavily from this step on. Database content was created in this step and used and made more accurate in next steps. Database contained about 270 entries.

In Step 5 marketing plan oriented mainly towards ICT and Internet's use was developed. Plan was oriented towards potential new partners located in step 4. "Value" of each partner for small business was evaluated (for each market and product line), which resulted also in order in which they will be contacted in next step.

As general approach 1:1 direct marketing was selected. For this purpose Web presentations in 3 languages were prepared in Quickplace. Collaboration technology is used in this case also for promotion. Individual presentations run in separate "rooms", which allow for great degree of personalization. Presentations are oriented towards small segment or in some cases even toward one (1:1 marketing) potential customer.

In step 6 the market plan was executed as planned, thus executing the "information step" of market transaction. Next transaction steps were executed mostly by tradition means, supported by e-mail.

Afterwards the results of the project were evaluated. The project achievements are shortly summarized below.

### 5.1 Project Results

Project's outcome can be – even taking into account some real-life limitations and shortcomings – evaluated

positively. Main project's goals have been attained

- method was developed
- small business has found new markets. At project conclusion there were 3 very promising negotiations under way regarding foreign markets which resulted in contracts later. One large contract has been signed in the home market. In this case the knowledge about the types of potential customers gained on international markets have led to contact in the home market with the type of partner which has not been contacted before.
- use of Internet – based ICT and Internet marketing for support of commercial activities has been demonstrated to small business and successfully used for gaining business benefits.

## 6. CONCLUSION

Based on results of practical verification the method can be evaluated as successful and as a useful tool for support of small business's commercial activities.

However implementation success is influenced by several success factors, some of which are basically critical (CSF – Critical Success Factors). As we have learnt, the basic CSF are the following:

CSF – global (in small business's country)

- the basic „support“ of small business's activities, i.e. state policies, legislation, taxes, governmental support
- this support strongly influences the way of project financing (which is critical). Financing can be provided by
  - o administration (state, region, Chamber of Commerce) – partly or entirely
  - o small business – partly or entirely
  - o sponsor i.e. ICT producer (as was the case of our project) or other – partly or entirely

CSF – small business

- fulfilment of basic requirements for expansion to new markets from production point of view, i.e. product which can compete with the products on international markets (in terms of quality, technology, price, after-sale service etc.), sufficient production capacity, ability to deliver product according to specific requirements of customers
- real interest in expansion to new markets
- strong support of small business management
- willingness of small business employees to take part in project activities and learn new approaches

- quick and qualified reactions to outside stimuli (e.g. reactions to questions and requirements of potential customers/partners)
- project effort and it's length of time depends on level of knowledge of small business employees especially in areas concerned (marketing, ICT, foreign languages for new markets)

CSF – consulting team

- good project management
- qualification of team's members and their „entrepreneurial“ approach
- language qualification (for new markets) or possibility of external provision (for not so common languages)
- team spirit

Based also on results of this case our University has launched an open „Program of cooperation of Universities and Small Businesses“ called **eMSP**. Program is opened to any University in the Czech Republic, small businesses, administration, industry – producers, suppliers and offers services oriented towards support of various small business's activities.

### ABSTRACT

In this paper, the concept and development of CRM (customer relationship management) are discussed, we defined a customer "lead" concept which emphasized the inter-connection of downstream and upstream processes of our customers. It is pointed out that the key point in CRM is the customer lead management in the software design and implementation. Based on this perspective, the processes of lead processing, lead management, and inside lead management are further elaborated, analyzed and their models are proposed. The problem of analyzing customers' behavior is also studied. Hence a simplified and lean integrated CRM software process is finally given, and this integrated model can be used to build CRM software for small and medium-sized manufacturing enterprises.

Keywords: CRM, Customer Relationship, Lean Model, Business Process Management

### 1. INTRODUCTION

Discussions on customer relationship management (CRM) have been going on for several years. International studies have tended to focus on the management function of CRM and its management characteristics<sup>[1][2]</sup>, and less on analyzing the structure and processes of such a system. We rarely see more in-depth research or thoughts on system design in the area, although CRM solutions have been developed by many software companies.

Referring to SAP company's CRM materials<sup>[3]</sup>, online help document<sup>[4]</sup>, and the Siebel company's Demo software<sup>[5]</sup>, we study and analyze the structure of CRM software. This paper emphasizes the re-construction of the CRM concept and provides a basic process framework of CRM model suitable for analyzing small and medium-sized manufacturing enterprises (SME). A typical manufacturing enterprise means a company has post-sales service and permits customers to configure the product they need. The basic process means a general framework, not taking industry characters and more complex processes into account. Generally, CRM software consists of three levels: the operating level, the level of analysis, and the level of cooperation. The model discussed here contains only an operating level, with little analytical function.

The object of building a lean, simplified model is to integrate the functions of marketing, sales, service, and configuration in an enterprise. Enterprise marketing and sales management will then be promoted from the departmental to the enterprise level. Another object is to make CRM software easier to understand, because managers may find it difficult to understand how to operate an enterprise supported by modern IT technology, which may lead to great changes in the relationship an enterprise has with its customers.

It should be pointed out that CRM software is just a software tool. What this paper discusses is the software design, development and implementation processes and how to improve them to help manage business flows in an enterprise.

### 2. MODEL STRUCTURE ANALYSIS

The first difficulty in modeling is how to describe the "customer" and "customer relationship." The words "focused with customer" can be seen in every paper on CRM, but left un-resolved are the questions of what a customer is, what a customer relationship is, how such a relationship is to be made the focus in the software.

Contact Center	Phone	Internet	Direct Contact
Marketing activity / Marketing Department	Tele-Marketing	Internet marketing	
Sales activity / Sales Department	Tele-Sales	Internet Sales	Mobile Sales
Service activity / Service department	Service Interaction Center	Internet customer self service	Mobile service

Fig1. Contact Center Structure

Also less discussed is how to build the process structure in CRM software to realize the concept of "centering." We see many variations software, but there are fewer papers describing why they are designed to look the way they do. In the following, we attempt to conduct such analysis of the CRM software. "Centered" should mean the monitoring, management and response to the feedback from the customer, i.e., the market. First, enterprises should be able to monitor the feedback from each "connection" between departments and the customer. The feedback is obtained by the connection, and the relationship is also from the connection, so the model must be related to the connect center. The model in the paper is a 3×3 connect center (Fig. 1) that covers almost all functions and various corresponding methods of connecting. Though there

may be only part of them in a real enterprise, it will not affect the discussion behind. The system should be able to manage the incoming customer information and send

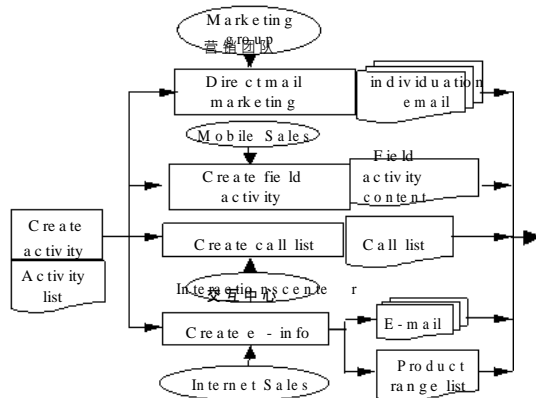

Fig2. Sending clue process in the Marketing level

it quickly to the corresponding stages, as well as give a response.

## 2.1 The Clue and Character

A careful analysis of the function of the connection center, which has a 3×3 connecting function (in all orientations) with customers, reveals that all of the results of its operations (on information flow) can be abstracted in one word – “clue.” Each piece of incoming information has its own source, and each piece of information that is sent has its own destination; they connect customers just like a invisible cobweb, regardless of whether or not a sales order is made. The process of forming a relationship between the customer and the enterprise is: connecting - understanding - making a relationship - exchanging action, so the clue is what we want to find – the basis of the customer “relationship.”

The reason why we emphasis the concept of the “clue” is also because it supplies us with a new prespective from which to rethink the design of CRM software.

Let us re-examine the concept of customer relation- ship management. Although not defined exactly, the “relationship” is, in fact, related to information on the customer and to the current and past connections between enterprise and its customers. Therefore, to some extent, we can say: to CRM software, customer relationship management is the processing and management to customer “clue”. Centered with customer, to the model, means centered with connecting, with clues, to complete monitoring, and replying the customer information in real time. This point should be the center of the design of the CRM process model; its software management process design should address this point. The accumulation of clues is also one resource of an enterprise, and the management of such clues promotes the management of the relationship between the enterprise and customer from the level of the department to the level of the enterprise. For the

same reason, an analysis of the enterprise’s relationship with its customers should not only focus on those with an order history, but on all customers who used to relate to the enterprise. This is because the aim of marketing is to enlarge the customer group.

Clues can be divided into three parts by the time of connection: connecting now – current clues; connecting in history – database clues; marketing connecting, aimed at enlarging the number of sales orders, and customer group based on customer classification and taste (target group), which are obtained by computations based on current and historical data to yield future clues.

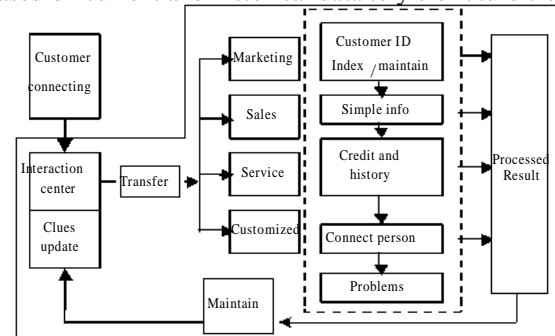

Fig3. Clue Receiving Process

The clues can also be divided into two parts based on inputs and outputs to the software system:

The first is sending clues. This part also covers two parts: answers to daily business processing; and marketing action information to obtain more customers. The process, which an enterprise needs to maintain and enlarge its market share, is illustrated in Fig 2.

The second part consists of coming clues. It also includes two parts: inquiries about daily business products or services (information less related to sales orders); and receiving clues, which are information about sales orders or plans for sales orders. The process is illustrated in Fig. 3, where the process in the dashed line block indicates the parts shared among several departments.

## 2.2 The Process to Manage Clues

The clues can be divided into available clues and general clues (not taking garbage clues into account). The available clues refer to the clues thought to have been changed to sales orders with a larger possibility, and the rest are general clues. But general clues yesterday may be available clues today.

### 2.2.1 The Process of Dealing with Clues

The processing of clues by CRM software may be divided into two levels: marketing level processing and sales level processing. We can then obtain two methods: 1) Medium-sized enterprises can first deal with the clues at the marketing level, and determine the clues that are available for transferring to the sales level. The sales

level then determines the clues that are most likely to lead to sales orders and to one-to-one services (two-level processing). 2) Small enterprise always need one level of processing, i.e., sales-level processing. As to the word “clues,” Siebel’s Demo refers to it as opportunity, SAP refers to the clues available in market level as lead, and to clues available at the sales level as opportunities. We define clue processing process based on the two-level process of clues. The evaluation process in such a system (divided market and sales) can be shown as follows: (the perform action in the marketing level can be seen in fig 2)

Therefore, in the process from marketing to feed-back, and from feedback to sales order, all exchanges are arranged to be completed from the connect center. If managed better, the clues in the process can all be recorded.

## 2.2.2 The Customer Characters in Clues

The customers of an enterprise always mean those with a history of commercial exchanges with that enterprise, but the concept of the customer in CRM is rather different. Fig. 4 shows the different concepts of the

Fig4. Inner-relation among different customers

customer and the inner relationship among them: the connecting customer is the total set of clue; the order customer means those with a sales relationship; service

customer and customizing customer are obviously sub-sets of order customer. Enterprises can select interesting groups of customers from different levels in Fig. 4 when they want to classify customers, but on the other hand, this will also show at least some of their attitude towards operations and the marketing environment, allowing enterprises to select subject products and target groups from various customer levels.

- z Pessimistic attitude: selecting a target group from the order customers, with the process of sending clues aimed at those customers. The object is to first fix upon the customers, then enlarge the market share. At the basis of the theory is the belief that the cost of developing a new customer is five times the cost of maintaining an old customer, and that 20% of the customers produce 80% of the profits of an enterprise. Such method is always adopted in a bad market environment. maintaining a old customer, 20% customers produce 80% profit of enterprise. Such method is always adopted on the bad market environment.
- z General attitude: selecting a target group from the order customers, with the group of clue customers also the same as that of the connecting customers.

The aim is to enlarge customer term furthermore at the time of fixing its own customer term. The advantage is that an enterprise can get extra customers, besides their original customers, and need not worry about omitting the requirements of the original customers.

- z The optimistic attitude: selecting a target group from the connecting customers, where in the sending of clues, the customer group is also the connecting group. Its object is to enlarge market share and the definition of the customer. In better market conditions, such a method will generally be adopted. The defect is that the target group obtained from clue customer may be some different from that obtained from order customers, or may even cover the requirements of the original customers.

## 2.2.3 The Managing Process To Clues

The model’s Object aims to integrate enterprise’s marketing, sales, service, configuration and analysis method into one frame. From SAP’s training material<sup>[3]</sup>, the clue can be managed by following process. First following concept should be given at least in the model.

- z Marketing- to enlarge market, it is decided by enterprise stratagem, operating object and it own resource and capability, and its document is market planning.
- z Campaign- to develop a market needs several campaigns, each organized campaign aims to a special subject product and target group, those customer group is got by computing in special arithmetic, and refer to the outside analysis information and the third analysis result, its document is campaign plan;
- z Action- a campaign is composed of a series of actions, and its document is action content.
- z Subject product- one kind or a series of product planned to push up (usually are higher ROI product);

Target group- a kind of classified customer got by computing the interesting of connecting clue customer and history customer data, its document is customer list;

Their relating is shown in Fig 5. The planned action is performed in sending clue process of marketing part(fig 2), when the campaign performed. And each action should be affirmed in all sending process to make sure it is performed. The market and campaign can be combined into one level clue management in some small system case. The work that needs to be performed after sending is the collection and analysis of clues on feedback.

## 2.2.4 The Inside Process of Managing Clues

From the literature review of SAP material<sup>[3]</sup> and Siebel’s Demo<sup>[5]</sup>, the inside management of clues can be adopted following a proper structure. The following

information are required to be in the CRM database:

- z Clue—a clue code is a directly connecting code for customer by various of channel and connecting media such as call numbers, mobile numbers, email addresses, and so on, so that the system can find the customer code using each clue;
- z Customer code — may directly index the customer's enterprise information, enterprise account, and connecting history;
- z Connecting person — there may be several connecting persons in an enterprise, who may be responsible for different businesses or for the same business; the system can find a list of connecting persons by customer code, in case this is needed.

When a connection occurs (taking call numbers as an example), the system should list those customer enterprises that have a similar call number as the coming number, and allow the receiver of the call to read messages related to the incoming call, such as the company code, simple information about the company, the company's credit status, and come of its commercial or connecting history. Furthermore, should allow him or her to read those records about the connecting people before and as part of the process of exchanging information (the clues involved are in the clue database illustrated in Fig. 5; its process is illustrated in Fig. 3). The advantage of this is that a business person (the receiver of the call) in same role can quickly know with whom and with which company he is communicating, and know its connecting history and the level of its relation- ship with his own company. From the simple record, he can anticipate what will be discussed, what questions will be asked, where the difficulties may lie, and the solutions previously given, and so on. Thus, the problem can be quickly affirmed and a new solution will be given.

### 2.3 A Comparion with ERP

Based on the above discussion, we can make simple comparisons between the ERP and CRM software.

- 1) The difference in aim: ERP is software that is based on process and centered on product management; CRM is based on process, and centered on clue management.
- 2) The difference in customer concept: customers in ERP always mean those who have an order history -certain customers; customers in CRM mean clue customers who used to connect to the enterprise -uncertain customers. There is more information on future customers in CRM.
- 3) The difference in information processed: the information processed in an ERP system is information that is currently useful (a series process after the making of an order), while the information in a CRM system is mostly currently useless, or useless forever, but no one knows which part may be useful and which part may be useless.
- 4) The difference in input/output: in an ERP system, orders are the input and products are the output; in

a CRM system, clues are the input and sales orders are the output. So the interface between ERP software and CRM software should be the sales order (as defined earlier).

- 5) The difference in model: the ERP model shows the integration of the whole enterprise process; and the CRM model shows the integration of the whole market and the sales process.
- 6) The difference in reference. The ERP model addresses enterprise business management framework supported by IT; while the CRM model addresses to the market and sales business management framework supported by IT.

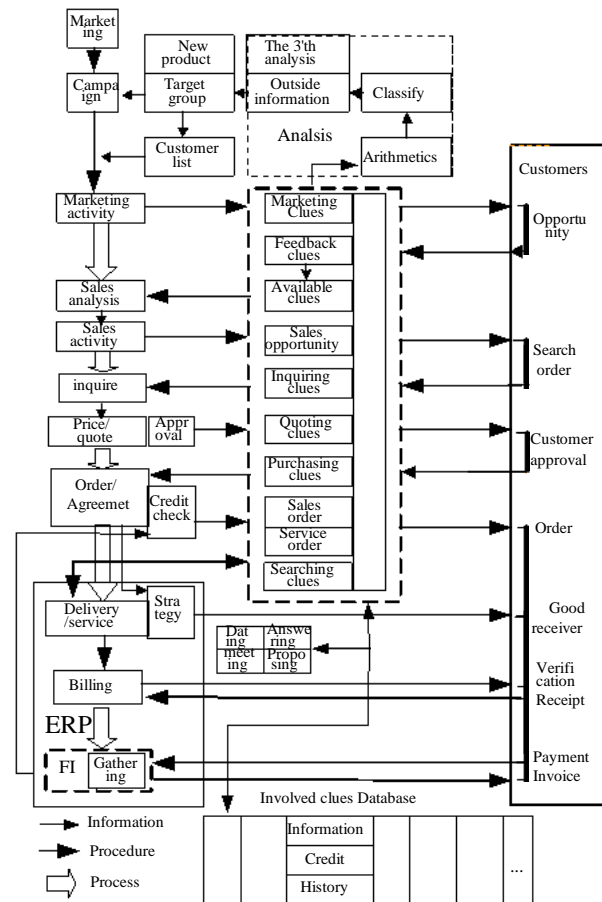

Fig5 CRM software simplified process model

### 3. THE INTEGRATED PROCESS MODEL AND ITS APPLICATIONS

A lean simplified, integrated process model that summarizes the above analysis is shown in Fig. 5. The model takes into account the enterprise functions of marketing, sales, services, customer configuration, and analysis, in order to make a CRM integrated process framework designed from the market orientation of the enterprises and customer orders. In Fig. 5, the thick line represents the process, the thin line represents information, and the dashed line box represents connecting center and its corresponding receiving and sending processes. Besides the marketing sending process, the marketing part also has the function of dealing with

general clues. Its result may be a simple answer: the giving of a suggestion, fixing a time for a face-to-face talk, or arranging a small meeting. The total process in Fig. 5 is as follows.

When planning a market activity, the people making the analysis begin from the clue database, refer to outside information and obtain the subject product and classified target group (customer group). They then come up with the object of the campaign, and organize promotions to reach the designated group of customers. In order to attain the objectives of the campaign, the market department should organize a series of corresponding actions, design corresponding action content, and perform them through the connecting center. As the campaign proceeds in all directions, in this target group old customers gain a new understanding and new customers who become interested in the subject product may connect to the enterprise's marketing department. The marketing department analyzes those clues on feedback, selects available ones, and transfers them to sales department. Those making inquiries are transferred directly to the sales department. The sales department studies this information in order to determine its own target group, then organizes corresponding actions in order to turn opportunities into sales orders.

The sales department also has the problem of receiving feedback. After orders arrive, CRM transfers the information to ERP. The ERP system completes the translation from orders to products and then to corresponding function. CRM takes the corresponding records, in case the customer inquires about it. Of course, the system should have the ability to compute costs, to evaluate the market and the effect of the campaigns. Obviously, in this the model, CRM cannot complete the order independently, so this part should have an interface to the ERP. The interface is not just a data interface, but needs to ensure process and organization, otherwise the system can only transfer data, but not complete the business processes. In fact, we can refer to the SAP's mapping method between SD module organization structure and that of the CRM<sup>[3,4]</sup>.

The sales part in CRM should have some similarity with that in the ERP. For example, the processing to inquiring/quotation, processing to order and so on: customer inquiring-enterprise quotation refers to the commercial history- customer making PO (purchasing order)- sales people searching inventory- enterprises sending SOs (sales orders) - the sales order to ERP system. The order is the output of the CRM software, and the later one is in the ERP manufacturing process. The service part has its own process, and is also processed in the flow of information, until the SO's are sent out. Service orders in a manufacture industry are

always related to manufacture orders: service order processing-resource planning-in site service completion and affirmed -- billing -- account receivable.

#### 4. CONCLUSION

A lean, simplified process model of CRM software has been proposed, and an analysis of CRM using a "clue" concept has been given in this paper. Our greatest contribution would be the concept of the "clue": for the database built based on connections is the basis upon which an enterprise analyzes customer behavior and characteristics, and is also the basis used to integrate and predict, and establish customer "relationship management." In today's ERP/MRP II software which is based on process and centered on products, it is essential for monitoring performance in real time, reacting in time to the status of the market, customer status, and customer feedback to form a CRM core management framework using the process and centered on customers (clues). We can see that CRM concepts, methods, and meanings may change with time, technology, and customer requirements, or the changes may even introduce a change in the structure of the CRM model, but these changes can be accommodated with a lean and simplified structure described in this research.

### ABSTRACT

Healthcare industry has unique characteristic about human's life. Any mistake or medical error will cause the irretrievable regret. Patient safety is the most important issue in recent years. Because the uncertainty of disease occur, the demand of healthcare need, location and types are changed frequently. By the pressure of "Self Management Plan", how to make limited healthcare more effectiveness and efficiency is critical for survival. Radio Frequency Identification (RFID) can be able to provide to identify, tracking and tracing for patient or medical objects directly and continuously. RFID is made object wisdom and process automation. It debase the cost of collect data from first-line in tradition MIS.

RFID in Taiwan is more famous. There are four kinds of applications in healthcare industry. Some of them will be the killer application when government's policy trigger and industry full-scale implement in the future. There are six hospitals deploy RFID in pilot plans by government support. And there are still some necks of bottle in deployment. The research assisted by foreign research and extracts by the experience in expert interview. We point out the critical deployment factors by five dimensions, including: system technology (system readable rate, frequency limitation, instrument interference & Human healthy, and transmission distance), system cost, common standard, health industry infrastructure and system integrate, and the issues in privacy and security by patient. The future research tries to find out the total solution to deploy RFID in healthcare industry to build up the "patient safety healthcare environment".

**Keywords:** Radio Frequency Identification (RFID), patient safety, healthcare industry, medical error, bar code

### 1 INTRODUCTION

Healthcare industry is related to the person's life closely. Any mistake or medical error will cause the irretrievable regret. Longer work time and work pressure made medical errors and negligence often happened in Hospitals. Healthcare is a high human concentrated industry. There are a lot of team works and coordination together from emergency medicine, outpatient care and inpatient care in hospitals. The report of Institute of Medicine (IOM) in "To Err is Human-building a safer health system" indicates that medical error often happens on bad communication and artificial negligence [6].

Patient safety is the most important issue from World Health Organization (WHO), European, America and other nations in recent years. After experiencing the storm of SARS, beating the wrong needle and giving the wrong drug...etc. The healthy quality and patient safety subjects are more valued by the public gradually. "Department of Health" considerably pays more attention to patient safety, and announces five execute goals in annual plans for government policy in 2004 [2].

Healthcare industry has his unique characteristic. Hospital is a place that people care of people. The healthcare service can't save and shift. Because the uncertainty of disease occur, the demand of healthcare need, location and types are change frequently, so the maximum difference between healthcare and others

industry is the uncertainty of medical demands [5]. There is high inside knowledge and entry barrier in healthcare industry. Computerized systems have capacity to augment the physician's capabilities to reduce the error rate for the advantage over humans, include: never forget, never get tired, and make no mistakes [8].

Hospitals in Taiwan had long history and abundant experience to import Hospital Information System (HIS) and Electronic Healthcare Record (EHR) with IT. But, there are more competitive and high pressures in hospitals in Taiwan by the limited income for healthcare insurance in "Total amount payment method", "Self Management Plan". How to deploy information technology IT to assist specialists in hospital working more effectiveness and efficiency to increase capability in limited medical resource and control operation cost cautious are the most famous research issues to the scholars in healthcare information management and healthcare service management [1].

Now, HIS can purely support work for operation level or management level. But, the most bottlenecks to implement information system in hospitals is that HIS can't handle the information about object name, time and location correctly including medical workers, patients and pharmaceuticals. Then it's hard to advance the capability for HIS to statistics, analysis and decision support, even more than strategy level.

Radio Frequency Identification (RFID) is one of the top

ten technologies in this century [14]. RFID is a kind of wireless technology by using radio frequency (RF) to identify objects. RFID can be able to provide to identify, tracking and tracing for patient or medical objects directly and continuously [1]. The characteristic of RFID is made object wisdom and process automation. RFID can reduce the cost of collect data from first-line in tradition MIS and have dramatic potential to great efficiency and profit in supply chain management (SCM) from manufacturer, logistics to retailer [4].

RFID can decrease medical errors, promote healthcare quality, and make the healthcare process automatic and optimize to save amounts of work in data collection, entry, integrity and confirmation such as patient identification, the three reads and five checks when giving pharmaceuticals, the data exchanged by patient referral...etc. By the characteristic of PPI (Positive Patient Identification) and POC (Point of Care)[16], RFID technology makes the maximum effect on HIS to deliver information at right time, real time and any time by reduce the time in data entry, object identify and make healthcare process visibility.

RFID is not a new technology, but it's a new revolution for application. By the same standard, protocol and communication language, there will be a strong impact for our life. Like the evolution for geographic commerce, electronic commerce (EC), mobile commerce to ultimate commerce, there's also extend to "U-healthcare"[21]. There are 4U in healthcare which includes: "Ubiquity" healthcare and service, "Uniqueness"EHR, "Unison"information and patient integration, and "Universality"healthcare environment. RFID provides "Competitive Intelligence"to decision maker and makes "Quick Response (QR)" for healthcare market demand.

## 2 RFID IN TAIWAN

RFID in Taiwan is more and more famous. Taiwan government provides both reward and investment by "Ministry of Economic Affairs" (MOEA). The substratum of administrations in MOEA are "Department of Commerce", "Department of Industry Technology", and "Industrial Development Bureau"[30]. The direction of policy in "Council for Economic Planning and Development to president" and the conclusion in "Science and technology Advisory Group of Executive Yuan" in "2003 SRB (Strategic Review Board ) meetings" also promote RFID to an advance and significant development in Taiwan[23].

The "Executive Yuan" (the Cabinet) in Taiwan promulgated "The vision in Taiwan of strategy service industry in 2010". MOEA established a cross-division RFID promotion team. The three important guide lines are "The Alliance of Supply Chain, (S plan) ", "The research and application in RFID platform, (R plan)", and "Telemetry, Health tourism, Integrated

medical system in Healthcare , (THIS plan)"[23].

There are different RFID industry orientation in different core development fields. RFID industry can discriminate in five divisions: RFID Tag (chip/die, antenna, attach, testing, convert), Reader (RF circuit design, digital circuit design, API development, and antenna module), Middleware (like SUN), System Integration (like IBM), Application Software (like Oracle), and Consultant (like Auto-ID lab).

Taiwan has maturely knowledge for RFID in semiconductor design, memory design, and specialized wafer production, electronic fabrication, software development, and system integration. Wireless and communication industry provide the capability of RF design, antenna design and field testing. Automatic equipment industry also possesses packaging and testing ability to cost down and increase production [19].

"Executive Yuan" formed RFID technology research and industry application alliance include six special interest groups (SIGs) in Taiwan, including with: Process equipment and Material SIG, Design and Manufacturing SIG, System Integration SIG, Supply Chain SIG, Testing and Certification SIG, and Industry Information SIG [32].

Many foreign information corporations also build up RFID research centers in Taiwan by the "International Innovation and R&D Base Plan" in "Challenge 2008-National Development plan"[22]. The enterprises include Oracle, SUN, HP, and Microsoft... etc. One of Auto-ID labs is in Fudan University, Shanghai. Two sites cross-strait of China are the main base of manufacturing center for foreign corporations. There will be many RFID technology developments and success application to paradigm shifts both in china cross-strait in nearly future.

## 3 RFID IN HEALTHCARE

### 3.1 The trigger of RFID in healthcare

There are no issues more important and popular than patient safety in Taiwan or foreign abroad. HIMSS patient safety survey indicates bar codes and CPOE (Computerized Provider Order Entry) have potential to improve patient safety [15]. Frank Kuo indicate five applications of RFID to increase patient safety by the famous seven patient safety goals in JACHO 2004, which including blood management, drugs management, surgical operation management, infection management, and medical equipment management [2]. RFID can also provide functions to satisfy three main demand of FDA's 21<sup>st</sup> century approach to patient safety like automatic data collection; partnerships with other entities (government agencies, healthcare providers, and payer organizations); and enhanced communication[26]. Wal-Mart requests the providers of front hundred

pharmaceuticals must deploy RFID in package with EPC standard, Read-Write passive tag (class2) before January 2005[27]. Accenture Technology Lab makes up the alliance of the biggest of eleven pharmaceutical manufacturing, distributions and hospitals [9]. Healthcare Distribution Management Association (HDMA) who constructs the health products and distribution standard to order that every pharmaceutical must paste RFID tag by case level of pharmaceutical in 2007[33]. The regulations of the "Food and Drug Administration (FDA)" in USA are even stricter to item level [27].

The specially report of "ID TechEx" estimate the application market of healthcare in America medical industry in 2010 will be arrive at \$ 86.3 billion[29]. By the above of the pharmaceutical supply chain with RFID, it's a trigger to detonate a great quantity of the downstream hospital implement RFID. So the questions of hospital aren't either or not to deploy with RFID, that is when to do it? [20]

### 3.2 The development in healthcare in Taiwan

The development of RFID in Healthcare in Taiwan is just at the initiation stage. There are six hospitals proceeding to RFID pilot plans earlier by government support. The pilot development goals of them are patient identification, drug identification, contact history tracking, infection announce, and medical warehouse management [1].

During SARS period, "Ton Yen General Hospital" deployed RFID pilot plan which technique support by "Industrial Technology Research Institute (ITRI)" at the first. And then, "Taipei Veteran's General Hospital", "Taipei Medical University Hospital", "KFAYA cancer center", "Show-Chwan Healthcare System", and "Tri-Service General Hospital" proceed RFID plans by government support[34,35,36,37,38,39].

"The Promotional Committee of e-Business Standard in the Medical Industry" builds "the Common Trade Platform in the Medical Industry" by "E-Commerce counsel plan" in MOEA. Taiwan wants building pharmaceutical data exchange standard and environment by XML and web service to promote RSS (Reduced Space Symbology) and CS (Composite Symbology). The committee will try to integrate EAN.UCC standard to healthcare industry [25].

The development directions and application fields with RFID in healthcare can division into four parts:

#### (1) Biotechnology and Pharmaceutical Fields:

Chemical reagent tracking, Animal, cell, and patient tracking and compliance in clinical trails.

#### (2) Medical Supply Chain:

Pharmaceutical supply chain, Warehouse management,

Anti-counterfeiting, Blood bank management, and Monitoring radioactive isotopes. (Including drug and surgical dressings)

#### (3) Hospital Internal Management:

Patient identification and position, Drug compliance, Disease control, Coordination the medical device, and Clinical path optimization.

#### (4) Healthcare Service:

Disease control, Emergency medicine, Sensors and Telemedicine, Long-term care, and Community continuity care.

## 4 THE EXPERT INTERVIEW

RFID implement in healthcare still in initial stage. There s no ready case or completely success experience in healthcare. We proceeded depth expert interview by quality research method with 10 experts, which including chief of the hospital information department, and scholars with RFID research in healthcare information, and health service management in Taiwan. We find out the advantage and inferiority in RFID in healthcare.

After expert interview, we integrate, sort and analysis the view and opinions in expert. The mainly critical key point to deploy RFID in healthcare industry can be classified into five followings: System technology, implement cost, standard protocol, information infrastructure, and privacy protection. We discuss them as follows:

### 4.1 System technology

#### (1) System readable rate

The most special features of RFID system lies in non-line of sight. Radio frequency delivering in air-interface needs better channel coding and modulation to reduce the signal broken and noise. Currently the readable rate of RFID system can't reach 100%, and this also becomes a biggest obstacle to implement. There are a lot of primary factors which influence the system readable rate, including: the direction of transmission, air-interface, the characteristics of product, and the characteristics of operation (environment).

The electrical label and reader have the directivity so there is extreme difference on the reading angle (horizon, vertical, oblique). If the product was horizontal between each other and outward to the product, it could be improving the readable rate. In other words, these critical factors such as temperature, humidity, and electromagnetic interference (EMI) of external environment should be paid a lot of attention. On the other hand, if the electrical label is put on the counter of absorbent or metal that would be decreased the readable rate substantially. The other reasons that

make the low rate of reading such as the distance of transmission and the moving speed of tag.

Besides, distance, indoor environment, the design of antenna, and the direction of installing are also very important influence factors. We can't use the high power reader in hospitals. Therefore, while implementing system, they should depend on the electric wave strength, clinical path, the need of moving line, and the result on-the-spot test which make they decide the demand and the position of readers. So, to deploy RFID isn't only a technology, it's an art and experience.

## (2) Frequency limitation

The wireless channel belongs to the public wealth. The International Telecommunication Union (ITU) is all carried on the programming and allotment of the frequency application by the government supervisor organization. Using RFID hardware equipment needs passing license by the "Ministry of Transportation & Communications" in "The Directorate General of Telecommunications (DGT)".

There are open frequency in the industry, about scientific and medical (ISM) in 13.56MHz, 2.45GHz. Currently, 915MHz is a controlled radio frequency, but the Directorate General of Telecommunications (DGT) has already declared the end of the year will open the 922-928 MHz channel to provide the RFID usage in the end of the year [16].

## (3) Instrument interference & Human healthy

It is the most anxious reason that radio wave interferes of medical instruments interactive, and it also influences weak patient in the medical environment, too. The conclusion of FCC and IEEE didn't find out any evidence that "Non-Ionization Radiation" of the normal regulations usage will endanger the human body. But nobody and no research guarantee about it.

On the interference of the medical instruments, we need to advance the demonstration first before implementing RFID in hospitals. Then, we carry on ducting into the work and field-test. Hospitals can aim at first: Electric shock machines, electrocardiogram (EKG), breath machines, and IV Pumps etc equipment carries on the test, and measures its wireless delivers the data mistake rate (BER) and electromagnetism mutual interference (EMI) condition. Currently hospitals which have implementing RFID all did not find obvious influence. However, the telecommunication bureau and department of Health supervisor organization should ensure safety to relieve the misgiving by more professional research [12].

## (4) Transfer distance

The factors which influence transfer distance include: reader power, sensitive of RFID tag, and four factors above-mentioned that influence about system readable rate. There are two kinds of RFID tag type is passive

and active. Active has battery by itself, but passive hasn't. Under the common testing environment, the distance of passive tag of 13.56MHz is approximately 1m, and 915MHz (UHF) is about 5m; the distance of active tag that the 2.45GHz (Microwave) is about 3m. The active RFID tag with 915MHz can transfer close to 100m.

## 4.2 Implement cost

Recently, there are some developing hamper in the other industry, main reason is higher cost. Healthcare has strong relation with persons' life and any mistake or medical errors may cause the irretrievable regret to patients. Medical errors will be impact hospital's brand and decrease customer's confidence violently. Furthermore, Healthcare should belong to public-spirited wreath in nations, it should be considering how to value added in society, not just to earn money. Medical institutions need to promote medical quality, decrease medical errors, and raise working efficiency with sacred spirit. The potential benefit and reality must evaluate altogether.

But RFID tag cost still influence spread tempo. The method of production and the market scale of RFID are the key factors to cost down. Just like the noted question about "Chicken birth eggs first, or contrariwise egg result chicken." Auto-ID estimate at the threshold limit price is \$5 cents. But, the price of purchasing in market is still around 40 cents (or above). Taiwan government announces that "Quanta Computer" can already production RFID tag around \$5 cents [11].

Like the statement to implement EMR, and HIS before, the cost of maintain always be extreme high than initial deployment expense. When hospitals evaluate to deployment RFID, they should be realized the capability, function, budget, and characteristics of their demand. To ask for advice with consultation is greatly important.

## 4.3 Standard protocol

There is long history in RFID, and many nations had already established their standard specifications for RFID, such as ITS America, U.S. Department of Defense, AIDC, ISO, ANSI, and CEN...etc. Because EPC network has the special feature such as automatic data exchanging, it extensively applied in general so far. The standards such as the computer network infrastructures of EAN, UCC, and MIT Auto ID Center propose EPC Network. The standard of EPCglobal includes the coding structure on tag, air-interface, local interface, Savant, Physical Markup Language and the Object Naming Service (ONS) together with the Savant support network [24].

In the aspects of foreign medical industry, Health Industry Business Communications Council (HIBCC) establish common standard protocol of the medical care

environment and the protocol can communicate with ANSI, CEN, and HIBC[28]. Currently the domestic medical hospital has no common standard. However common coding format, it appears that data interchange among different HIS is more important at medical institutions. This needs the Department of Health and related supervisor organization to establish it as soon as possible.

#### 4.4 Information infrastructure

The complete infrastructures is a cornerstone to deploy RFID well, including: the network communication with common protocol, Health Information Network (HIN), PML server, ONS server, and the mechanism about audit and authentication, and un-interpolation. On the other hand, the backup mechanism should be established beforehand. Through the high utilization, stability, scalability of server system that can maintain a lot of data file, analysis and process.

By system integration view, the simple close loop system (single hospital inside) can be extended the open loop system (inter-hospitals by alliance). But it will substantially increase system complexity, expenses and timing significantly. However, it's only amplified on more effectively and reach the maximum revenue of investment (ROI) in implementing RFID, when the information infrastructure has been built up completely.

#### 4.5 Privacy protection

The right of privacy here can be divided into medical workers and patients. Medical institutions can control more complete and durable information of members in hospital by RFID, but also cause larger personal controversy of privacy. Medical industry has its particularity. Under the need of safeguarding the whole benefit of social, the public hygiene environment and medical science research etc, personal privacy is not placed into the initiative of position definitely while medical information privacy and personal right conflict mutually.

Besides, the questions in RFID about EMR data ownership, data security responsibility, data expiry date... etc, they also cause many controversies between medical care quality and the power of professional medical treatment from academy such as medical science, law, politics, science, technology and humanities etc.[3] The supervisor authorities should carry on the more thorough study about this, and have definite standard to let medical institutions to follow.

### 5 CONCLUSION

Like the chairman Mao Tse-tung in China who said: "The future is glory, but the road is complicated". And he also said: "Doing right direction, everything will be alright"[40]. To understand the development process

and constraints of RFID technology in healthcare, can let us deploy RFID correctly at right time, right place and right strategy model. Then, hospitals can possess best ROI, make the value added and acquire competitive advantage.

How to promote patient safety are the most important issues in healthcare in Taiwan. To maintain high healthcare quality is not to reach the goal in one step. To error is human. There are not the same reasons in medical error in each hospital. There is less medical adverse event in negligence by artificial to be announcement by hospitals. Now, the questions we aware are just like a nook in an iceberg. However, healthcare industry has unique characteristic about human's life. So there are maybe some "killer applications" in healthcare first. We point out the critical deployment factors by deploying RFID in healthcare. The future research tries to find out the solution to solve the questions in the paper above.

Integrating RFID with HIS will make patient more safety, and make healthcare more accuracy and efficiency, and less medical adverse event in negligence. We create an automatic healthcare mechanism to depend on five rights care quality, which include: right patient, right drugs, right dose, right time, and right route. The final vision is to create the sublime of dream by RFID assistance in the "patient safety healthcare environment".

#### ACKNOWLEDGEMENT

Thanks for the direct and inspire from the professor Hsin-Ginn Hwang, Cheng-Yuan Ku, Fan Wu and I-Chiu Chang in National Chung Cheng University (NCCU), and W.C Tsai in China Medical University (CMU).

And special thanks for the professor Yi-Long Huang, James Tsemeng Lin in National Tsing Hua University (NTHU); the professor Anthony Fu-Wha Han, Hsiao-Cheng D. Yu in National Chiao Tung University (NCTU); Shran Koung Chou in National Chengchi University (NCU)

Thanks the support from dear friends in 349-1 Lab in NCCU, "Green On Digt. Inc.", Fion Chou in Oracle.

### ABSTRACT

The present work proposes a model to compare means of many constructs that evaluate competitiveness of brands of the Brazilian chilled and frozen food industry. Such a model is based on a nomological network, which was built over the concepts pointed by [4] [13] [8], and [7] by the NUME – Marketing and Strategy Research Center of the Federal University of Minas Gerais – research group. Besides the validation of the new research instrument for gauging and generalization, it will be made an evaluation of brands – the ones well-positioned at the market – using the comparison of the indexes and averages of the nomological chain built for the companies, in relation to the following concepts: Tangibility (perception of packings, flavors and smells); Reliability in the Brand; Satisfaction; Loyalty; Image of the Brand; Perceived Value and Functional Conflict.

**Keywords:** competitiveness, food sector, nomological chain

### 1. INTRODUCTION

In reason of the elevated deregulation, the Brazilian food industry is highly competitive. This deregulation is a characteristic of the 'basic consuming goods', along with the short life cycle, maturity and oldness of the sector.

The food industry received, in the last years, a demand increment originated from the middle class population strata. And, with the productivity increase, the food could arrive to the final consumer with smaller costs [10].

Therefore, the emphasis doesn't just sets on the costs of the food, but it also covers the purchase services, storage, cleaning, preparation and commercialization.

In Brazil, there is a great number of companies with an assorted mix of products, which harshly dispute the customers' preference in the supermarkets' shelves.

The companies included in this research represent the leadership of the Brazilian market, they are the enterprises whose Brand names are: *Perdigão*, *Sadia* and *Seara*. The items appraised in these brands are the chilled and frozen meat products.

### 2. THE COMPANIES INVOLVED

Perdigão [16], founded in 1934, is a great manufacturer of poultry and pork byproducts. Along the years, the company has implemented a poultry and pork productive system, the so called vertical integration. Currently, the total number of integrated partners is of 6,810, and Perdigão has carried out a significant industrial expansion over these last 64 years. All in all the industrial complex comprises 12 meat and 2 soybean

processing units, 6 animal-feed factories, 12 incubator units and 27 company-owned poultry and pork farms.

Sadia [19] has been taking the leadership in several activities related to the food industry. It is among the largest food processing companies of Latin America, being one of Brazil's largest exporter. As a research – conducted by the English consulting firm Interbrand in 2001 – realizes, the brand Sadia was acclaimed as the most valuable company of the Brazilian food industry. Besides, according to the operational profile traced by the brokerage company Pilla Corretora de Valores Mobiliários e Câmbio, in the third quarter of 2002, Sadia was pointed as the national leader in the production and sale of frozen and chilled food products of poultry and pork meats, besides counting with the largest distribution network of frozen and chilled food products in the country.

Seara [20], founded in 1956, represents one of the largest national companies in the segment of poultry and processed meats (hams, sausages and salamis). Besides, it exports poultry cuts and pork meat. João Augusto Salles, responsible analyst for the sectors of banks and food products of the Brazilian consulting firm Lopes Filho e Associados, affirms that Seara is the largest exporter of pork of the country. It exports more pork meats than Sadia and Perdigão. Seara is a company of great stature and has its own seaport, in Santa Catarina, to export its production.

### 3. PROBLEM OF THE RESEARCH

The main question of this research is: *Are there meaningful differences between the averages of the brands? Does the one the brands occupy prominent position at all the constructs of clients' perceptions?*

#### 4. OBJECTIVES OF THE RESEARCH

With this research, the goal is to build a tool that could measure differences between competitive brands and prepare a new measure tool to the *commodity behavior sector*.

#### 5. CONSTRUCTS OF THE RESEARCH

In the present research there are constructs of different models. From the Model SERVQUAL [2], the constructs Tangible Aspects and Reliability were used. From the ACSIndex - American Consumer Satisfaction Index, proposed by [4], the constructs Loyalty, Satisfaction and Perceived Value were taken. The construct Image was retrieved of the conceptualization of [1], while the Functional Conflict came from [13] Relationship Model.

##### 5.1. Tangible Aspects and Reliability: The SERVQUAL Model

The first studies about quality of services were of authorship of [14] and had as objective to search for an integrative model in that area. Therefore, the managers and customers of four North American companies were questioned on the fundamental attributes of the service quality, being also brought up the existence of divergences between the two opinions. The following companies participated in the research: retail banks, credit card administrators, property brokers, and repair and maintenance of goods firms.

In a second phase of the research, [15] focused their studies in the measurement of Gap 5 (gap between the perceived and the expected service), appearing the famous equation:

$$Q = P - E \quad (1)$$

In other words, Quality = Perception - Expectations. Initially 97 items, referring to the external dimensions of the service quality, were generated. Later, the scale was refined and it came to a scale of 22 items. The grid of items contained in the research instrument reflected the following dimensions: Tangible Aspects, Reliability, Promptness, Guaranty and Empathy. Such dimensions are:

- Tangible Aspects: physical facilities, equipments and appearance of the company's personnel. When the consumer enters in contact with the atmosphere of a supplying company.
- Reliability: capacity and ability to implement the promised service in a safe and reliable way.
- Promptness: good will to aid the consumer and to provide ready attendance - to solve problems on time.

- Guaranty: employees' knowledge and courtesy and their ability to inspire credibility and trust - to assert that the service is safe and guaranteed.

- Empathy: individualized consideration and attention that the company renders to its consumers - fine-tuning of sympathy and understanding between supplier and customer.

In this study, only the Tangible and the Reliability Aspects were explored.

##### 5.2. Loyalty, Satisfaction and Perceived Value: ACSIndex

The Model of the ACSIndex - American Consumer Satisfaction Index - is proposed by [5]. That model intends to offer a base of uniform and comparable measurement for the customer's global satisfaction, besides pointing relationships of such construct with its main antecedents and consequents. Implicit in the model is the recognition that the customer's global satisfaction cannot be directly measured, being a latent variable requesting multiples indicators in its measurement. The most immediate and tangible result of the operationalization of that model is a score of the latent variable of the customer's global satisfaction, in terms, generic enough, for a comparison among supplying organizations, branches of activities, sectors and nations.

###### 5.2.1. Loyalty

The final relationship of the model is between the customer's complaints and their loyalty. The direction and the indication of that relationship depends on the service systems rendered to the customer and on the solution – by the supplier – of the clients complaints [4]. When the relationship is positive, the implication is that the supplier succeeded in transforming a customer that complains into a loyal customer. When the relationship is negative, the supplier worked with the situation in such a way that the negative situation became even worse, contributing to the loss of the customer's loyalty.

###### 5.2.2. Satisfaction

The customer's global satisfaction, as the central construct of the model is placed inside of a relationship chain that goes from its antecedents (expectations, quality and value perceived by the customer) to its consequences (complaints and the customer's loyalty). Of special interest in the model, beyond its own global satisfaction, is the explanation of the customer's loyalty, as very probable indicator of profitability [17]. With that structure, the model allows the ACSIndex to be tested under the nomological point of view. Nomological validity is the degree in that a construct behaves as predicted inside of a system of related constructs, the so-called nomological network [3].

### 5.2.3. Perceived Value

A second determinant of the customer's global satisfaction is the perceived value. This is the product perceived level of quality of the product in relation to its price. The factor price is incorporated to the perceived value, reinforcing the comparability of results among suppliers, branches of activities and sectors. It is supposed to be a positive association between the product's perceived value and the customer's global satisfaction.

### 5.3. Image: Lalande / Barich and Kotler

The author [11] defines image as being the mental repetition, usually weakened, of a sensation (or more exactly of a perception) previously experienced. Image can then, be considered, as being a certain way of appropriation of the reality for a certain subject, in other words, as perception phenomenon. Perception can be understood, according to [11], as an act in which the individual - organizing its present sensations, interpreting them, and complementing them with images and memories - opposes to an object that he/she spontaneously considers as different from itself - real and unknown.

Through the perception happens an internalization process - by the individual - of the received stimuli, that will make possible the formation of the image, through which he/she will recognize such incentives. The perception phenomenon is, according to [11], the identification of the reality; happening after the sensation phenomenon, when the individual will learn - through a selective process - some values present stimuli received and will aggregate to it other subjective values and internal objectives.

In that way, image can be considered as being the subjective vision of the objective reality. The reception of the emitted message will be formed, starting from the process of interpretation of that message, being then, modified, and acquiring its own version in the individual's conscience [11].

The image that the individual has of the real (symbolic and different vision from the reality) unchains an attitude of that individual towards the object - therefore, the image has then, the power to influence the individual's behavior [18].

The first image focuses linked to marketing appeared in the 1950s. The authors [6] verified that the consumers not only valued the physical, tangible aspect of the products they buy, but also the symbolic meanings attached to the brand of those products.

## 6. MODEL OF THE RESEARCH

Once the constructs have already been explicated, the adapted model is in the FIG.1.

Figure 1 - Adapted model

## 7. ANALYSIS RESULTS

### 7.1. Factor Analysis

In order to analyze interrelationships among a large number of variables, Factor Analysis was chosen as the statistical approach in this work. According to [9], the aim is to explain these variables in terms of their common dimensions, called factors. Hence, factors are dimensions that try to explicit the existent correlations between a group of variables. This process enables the researcher to lose the minimum of information.

A multivariate method included in the group of Factor Analysis is the Principal Component Analysis, which derives factors that contain small proportions of unique variance [9].

This method is recommended in case the objective is to determine the minimum number of factors (principal components), that answer for the maximum variance on the data for future multivariate analysis uses [12].

It is worth to remember that in TAB. 1 and 2, only the factor loadings for each question higher than 0.5 were kept in the table, showing a good correlation with each factor [9].

TAB.1 shows the Rotated Component Matrix. It shows how many factors were built by the collected data. Six factors were found, and this is a good result, once there are 7 constructs in this research. Only the loadings over 0,5 were maintained in the matrix, according to [9].

From the TAB.1, it's able to see some well dimensioned factor and others not so much. The first factor grouped several indicators from three different constructs (Tangibility, Reliability, and Loyalty). The second factor is related again with Tangibility and Reliability, both from the SERVQUAL model of [15]. Functional Conflict is totally explained by the third factor. The fourth factor is fragmented between Image and Satisfaction, with the fifth is clearly Perceived Value. The sixth is more related to Tangibility.

In order to reach a better result, a seven-factor rotated component matrix was forced in future factor analysis, as TAB. 2 displays.

**Table 1 - Rotated Component Matrix**

	Factors					
	1	2	3	4	5	6
The products packages are practical and easily handled						,556
The information in the packages correspond to what the products represent						,535
I consider the products of this company flavorful		,580				
The ready foods to eat have a pleasant smell		,748				
The color of the products of this company is pleasant		,783				
I believe in the quality of the products from this company		,607				
The products are safely packaged	,612					
The company keep their promises in its products	,586					
I recommend this company's products to my family and friends	,741					
When I come across new products of this company, I do not hesitate in buying and consuming them				,533		
I feel comfortable in recommending the products of this company to other people	,734					
I defend the products of this company when somebody makes negative commentaries about them						
If the press releases good news about this company, I am immediately inclined to believe in it	,514					
The logo of the company means a serious presentation to me, and of good reputation				,512		
When I go shopping, I search in order to identify the products of this company on the shelf						
For me, this company has a positive image				,606		
I am satisfied with the existence of a company like this supplying food				,732		

	Factors					
	1	2	3	4	5	6
If there aren't any offers of products from this company, I will not hesitate in buying products from another company						-,750
The products of this company satisfy my expectations				,722		
I believe the price charged for the products of this company is fair, considering the quality offered					,844	
The price I pay for the products from this company is within my expectations					,882	
I believe that, if I detect some problem in a product, the company will solve it promptly			,810			
I believe that my suggestions to improve the products will be Heard by the company			,823			
I believe that the company, in case I complain, will pay attention to me			,918			

**Table 2 - Rotated Component Matrix – Forcing 7 factors**

	Factors						
	1	2	3	4	5	6	7
The products packages are practical and easily handled							,555
The information in the packages correspond to what the products represent							,575
The products are safely packaged	,661						
I consider the products of this company flavorful	,539						
The ready foods to eat have a pleasant smell				,820			
The color of the products of this company is pleasant				,750			
I believe in the quality of the products from this company	,692						

	Factors						
	1	2	3	4	5	6	7
The company keep their promises in its products	,687						
I recommend this company's products to my family and friends	,606				,521		
When I come across new products of this company, I do not hesitate in buying and consuming them							
I feel comfortable in recommending the products of this company to other people	,688						
I defend the products of this company when somebody makes negative commentaries about them					,712		
If the press releases good news about this company, I am immediately inclined to believe in it					,655		
The logo of the company means a serious presentation to me, and of good reputation			,512				
When I go shopping, I search in order to identify the products of this company on the shelf							
For me, this company has a positive image			,614				
I am satisfied with the existence of a company like this supplying food			,766				
If there aren't any offers of products from this company, I will not hesitate in buying products from another company							-,742
The products of this company satisfy my expectations			,723				

	Factors						
	1	2	3	4	5	6	7
I believe the price charged for the products of this company is fair, considering the quality offered						,856	
The price I pay for the products from this company is within my expectations						,893	
I believe that, if I detect some problem in a product, the company will solve it promptly		,812					
I believe that my suggestions to improve the products will be Heard by the company		,819					
I believe that the company, in case I complain, will pay attention to me		,917					

## 7.2 Means Comparison

For a means comparison, it was used the Analysis of Variance (ANOVA), a method to test the equality between means from three or more groups [21]. The hypothesis tested in ANOVA is related to the means between the different groups. If the calculated P Value is less than 0,05, one concludes, with 95% reliability, that at least one of the groups has the different mean compared to the others.

The ANOVA only verifies if there are significant differences between the groups; so, to point out which of them are different, it was used the Duncan's Multiple-Range Test, that compares all the pairs of involved means in a study of Analysis of Variance [22].

TAB. 3 shows that one company holds the best position in the ranking in relation to almost all the constructs, and three are tied up in the constructs Perceived Value and Functional Conflict. This shows that to invert the order it is necessary a significant investment from the company in the second position and even more from the third position, so that the company can enter the battle to be the first option of the customer. An option that the first position still has is to also be hegemonic in the two constructs where they are tied up, once the company looks for investments in this direction. Through a deep look on the TAB.3, it is easy to see that the leading company in the food sector (Sadia) has an average of perception, in almost all constructs, higher than the other companies. There was no significant difference

between Perceived Value and Functional Conflict among the three companies.

**Table 3 – ANOVA**

	Sadia	Perdigão	Seara	ANOVA (P Value)	Duncan's Method
TANG	24,8231	26,8719	28,0839	0,000	Sadia > Perdigão > Seara
RELIAB	18,3438	17,6283	15,8081	0,000	Sadia > Perdigão > Seara
LOYAL	12,4431	11,8700	10,2425	0,000	Sadia = Perdigão > Seara
IMAG	14,5600	13,7001	12,1394	0,000	Sadia > Perdigão > Seara
SATIS	12,9963	12,4318	11,4378	0,000	Sadia > Perdigão > Seara
PVAL	6,6775	6,6570	6,4005	0,676	There isn't significant difference
FUNCC	13,0395	12,9455	12,1006	0,063	There isn't significant difference

**Key:** Tang – Tangibility; Reliab - Reliability; Loyal – Loyalty; Imag – Image; Satis – Satisfaction; Pval – Perceived Value; Funcc – Functional Conflict.

### 7.3 Multiple Regression Analysis

Multiple Regression Analysis is a statistical tool used to measure the relationship between one dependent variable and several independent variables, called predictors [9]. The objective is to analyze the possible strong and weak relations between constructs. The regression equation's adjust quality is verified through R Square, which is the model for coefficient of determination. The method used in this analysis was Stepwise, that takes out the non-significant variables from the model.

TAB. 4 presents the regression equation with standardized coefficients, having the construct Image as the dependent variable and Tangibility, Reliability, Satisfaction and Quality as the predicting variables. In this context, it is important to observe the emphasis or major weight attributed to the predictors by the companies, in order to build the Image organization in the competitive market.

Through the results in the TAB. 4, we can observe that Seara suggests that builds its Image through its clients' Satisfaction. Besides, it emphasizes the Satisfaction perception with more emphasis than Perdigão and Sadia in building the Image construct, unlike the other companies, that give more importance to Tangibility than Seara does.

**Table 4 - Regression analysis for the Image of the companies - Standardized coefficients**

Perdigão	0,241 (0,000)	0,325 (0,000)	0,118 (0,044)	0,987	0,000
Sadia	0,222 (0,000)	0,318 (0,000)	0,188 (0,000)	0,993	0,000
Seara	0,125 (0,013)	0,317 (0,000)	0,354 (0,000)	0,977	0,000

TAB. 5 presents the regression equation with standardized coefficients, having the construct Loyalty as the dependent variable and Reliability, Perceived Value and Quality as the predicting variables. In this context, it is important to observe the emphasis or major weight attributed to the predictors by the companies, in order to build the Loyalty organization in the competitive market.

**Table 5 - Regression analysis for the Loyalty of the companies - Standardized coefficients**

Perdigão	0,599 (0,000)	0,201 (0,013)	0,965	0,000
Sadia	0,601 (0,000)	0,216 (0,011)	0,964	0,000
Seara	0,649 (0,000)		0,952	0,000

As we can see through the results showing in the table 5, the Loyalty to Perdigão and Sadia are based not only on Reliability, but also on Perceived Value, while Loyalty for Seara is directly linked only to Reliability.

Clients' Satisfaction for Sadia is more related to Reliability than the other companies, once Satisfaction for the others is also related to Tangibility.

Functional Conflict for Perdigão is more related to Tangibility, and for Seara is linked to Perceived Value. Only Sadia links Loyalty to Functional Conflict.

**Table 6 - Regression analysis for the Satisfaction of the companies**

Perdigão	0,497 (0,000)	0,132 (0,011)	0,969	0,000
Sadia	0,703 (0,000)		0,971	0,000
Seara	0,470 (0,000)	0,159 (0,009)	0,959	0,000

**Table 7 - Regression analysis for the Functional Conflict of the companies**

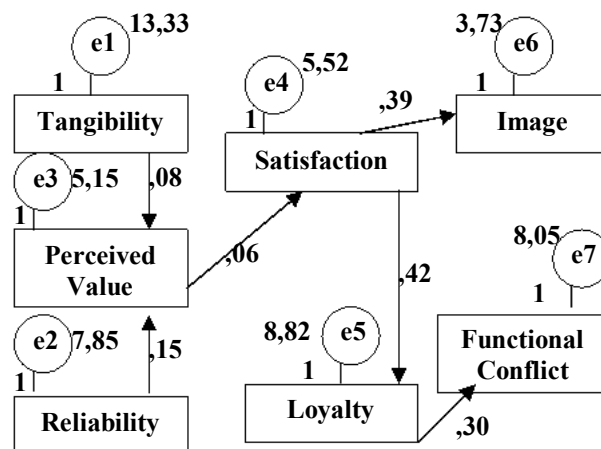

Perdigão	0,425 (0,000)	0,216 (0,028)		0,956	0,000
Sadia	0,324 (0,000)	0,196 (0,047)	0,207 (0,020)	0,957	0,000
Seara	0,322 (0,000)	0,624 (0,000)		0,944	0,000

#### 7.4. Structural Equations Modeling

SEM (*Structural Equation Modeling*) is a tool used in both academic and managerial research. According to [9], it is a multivariate technique which combines aspects of multiple regression analysis – examining dependence relations – and factorial analysis, in order to estimate several dependence relations interrelated simultaneously.

In this paper, the technique was used to verify – grouping the researched companies – the influence level of each construct in the other ones, and it also investigates stronger dependency relations from the proposed model.

FIG.2 presents the model with non-standardized coefficients which correspond to regression weights in multiple regression and they are expressed in terms of construct scale, variance in this case [9]. As scale varies from one construct to another, the comparison among coefficients becomes more difficult than using standardized coefficients (FIG. 3).

**Figure 2 – Model with non-standardized coefficients**

Model goodness of fit was unfavorable because of the results of Chi-Square Test and P Value lower than 5% (considering as a desirable value of significance level: Chi-Square = 665,197; Degrees of Freedom = 15; P Value = 0,000). Thus, the proposed theoretical model – in theoretical nomological chain – is considered not to be adjusted with empirical measurements.

In a general way, correlation coefficients presented are low and indicate a weak adjustment of theoretical linear model to the empirical data behavior. This work understands this as a limitation that should be investigated in a deeper way including new attempts of data mining in order to rotate the model with transformed variables. In spite of this limitation, we can see that for the values presented by the arrows (FIG.2) the biggest regression coefficient is the one that goes from Satisfaction to Loyalty, it means that Satisfaction explains 42% of Loyalty. Beta coefficient non-standardized from Satisfaction to Image is also high, thus Image is explained by 39% of the first construct. From those observations, it is possible to infer, with some limitations, that clients' Satisfaction for all the three companies implies in a higher Loyalty and it also contributes to construct a better company Image.

FIG.3 presents standardized coefficients where all of them have equal variances and they are useful to determine relative importance, but they are specific to each sample, so they are not used to comparison among samples (as non-standardized coefficients).

With standardized coefficients it is possible to verify that Satisfaction explains 42% of Image constructed by clients of researched companies, important managerial information. The number above "Image" box (.18) indicates that antecedent constructs together, in a Multiple Linear Regression, explain 18% of Image.

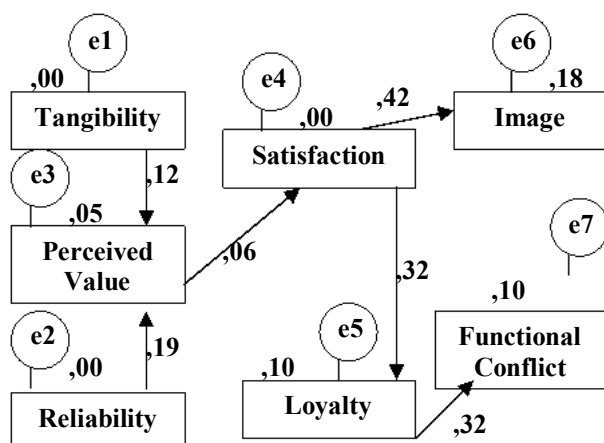

Figure 3 - Model with standardized coefficients

## 8. CONCLUSIONS

Analyzing all the results, it's clear that the perception of the respondents is equal to reality: Sadia continues to be the leader in the nourishing sector. This consideration is very important, once people aren't always able to differ objectively what is real in the market.

As we can see, Sadia detaches in the preference of consumers – the reasons are that Sadia has been applying resources in product development and quality in the Brazil market. Nowadays, it's becoming very difficult for the other competitors to obtain the leading position. The competitors keep launching products and innovating in a competitive market, but time has showed a stable position of Sadia in relation to the preference of consumers.

In Regression Analysis, it was confirmed that Sadia continues to be the leader in this food sector, and another information was observed (TAB. 4). This company gives more importance to Reliability to build its Image, although Perdigão, the second in ranking, has the higher coefficient in the analysis.

It was also observed that Loyalty really depends on a good level of Reliability, for all the three companies, important information to management decisions.

Structural Equations Modeling presented strong relations among constructs Satisfaction, Image and Loyalty. Thus, a satisfied client becomes loyal and builds a good company image.

In future studies, an experiment can try to measure possible unbalancing of this positioning order (commodities unbalancing).

# Theoretical Framework of Empirical Study on Consumer Behavior in Web-Based Commerce

Yuming Zhu, Peng Guo

Management School, Northwestern Polytechnical University, Xi'an 710072, China  
{zym1886, guopeng}@nwpu.edu.cn

## ABSTRACT

Web-based commerce has brought great challenges and opportunities to companies. To seize the opportunities, the company must work out well-conceived web-based marketing strategy, which, to great extent, relies on the good understanding of consumer behavior in web-based commerce. Based on general theoretical framework of study on consumer behavior and current achievement in this area both overseas and home, the theoretical framework of empirical study on consumer behavior in web-based commerce is put forth. In this theoretical framework, two dependent variables are determined as unplanned purchase and customers' intention to return, which are affected by two attitudinal variables, i.e. perceived control and shopping enjoyment. The two attitudinal variables are also affected by individual factors and web store factors, which also contain certain sub-factors. At the end of this paper, some suggestions on further study in this field are brought forward as well.

**Keywords:** theoretical framework, empirical study, consumer behavior, web-based commerce

## 1. INTRODUCTION

Along with high speed development of net technology and globalization, the portion of on-line sales in retail sector will become bigger and bigger. According to the information from U.S. Commerce Ministry at Nov. 21, 2003, the total on-line sales of U.S. was increased by 27% up to \$13.3 billion during the third quarter. In Europe, the on-line sales of 2003 are up to 70 billion Euros. In China, according to the survey of iResearch, the total on-line sales of 2003 were RMB0.79 billion. For 2004, the sales will exceed RMB1.6 billion<sup>[1]</sup>. Therefore, the web-based consumption has been bringing revolutionary changes and impacts on traditional ways of consumption. In business-to-consumer electronic commerce there have been two transformations: (1) the transformation of the consumer into a computer user, and (2) the transformation of the physical store into a phenomenon that is information technology intensive—in other words, a Web site. The new double role of consumer/computer user resulting from the first transformation is inherently complex and still not well understood. The second transformation concerns store technology. In the physical commercial world, the information technology used in a store is most often invisible to the consumer, whereas in e-commerce it has been moved to the foreground. To the consumer, the Web site, an information system, is a full representation of the store. Therefore, it is necessary to look at the interaction between consumer and store through the filter of user-technology interaction. Given these transformations, researchers need to combine the research streams of information systems, psychology, and marketing to study and understand on-line consumer behavior. The empirical study, which is widely used by western researchers, is just the required combination of studying. However, due to different environment, some results achieved through empirical study by western

researchers cannot be directly and simply applied in China.

## 2. ACHIEVEMENT ON CONSUMER BEHAVIOR ON WEB-BASED COMMERCE

At present, most of successful B2C companies are Western companies, such as AMAZON, DELL etc. There are two causes for this: (1) well-established credit system of paying, and (2) well-combined research and practice. By empirical study, the western researcher found that perceived control and shopping enjoyment can increase the intention of new Web customers to return, but seemingly does not influence repeat customers to return. They also found that a Web store that utilizes value-added search mechanisms and presents a positively challenging experience can increase customers' shopping enjoyment. Further, the more often customers return to a Web store, the more their shopping enjoyment is determined by their product involvement. Customers with low need specificity (i.e., who do not know what they are looking for) are more likely to use value-added search mechanisms. Finally, neither perceived control nor shopping enjoyment has any significant impact on unplanned purchases<sup>[3]</sup>.

In China, the researchers studied consumer behavior on web-based commerce from qualitative aspect and quantitative aspect respectively.

From qualitative aspect, the researchers found the following changes which have taken place in consumers' psychology: (1) personalized consumption prevailed; (2) initiative consumption increased; (3) stability of consumption psychology decreased; rapid switching speed; (4) chasing both convenience and enjoyment of consumption; (5) price still be one of most important factors. However, owing to characteristics of web-based

consumption, there must be certain psychological needs cannot be satisfied. For example, due to partial replacement of personal intercommunication, the social psychological needs can not be complied with to the full. In addition, the on-line shop cannot give consumer the feeling of being noticed and respected. The consumers cannot show their social status, achievement and dominance. Furthermore, less flexibility of pricing lead to dissatisfaction of consumers who like bargaining on the scene<sup>[4]</sup>.

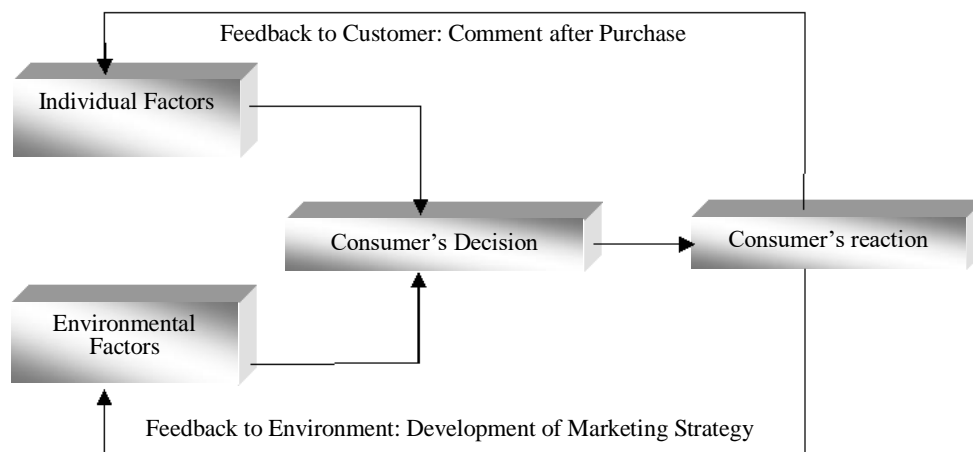

From quantitative aspect, the researchers also make certain achievement such as *web-based consumption: theoretical model and behavior analysis*, which is a book to sum up the findings of researchers of Harbin Institute of Technology. By using this mathematic model, the researchers found that the process of on-line consumption is a combined process of production and consumption, and a complicated process of ensuing of utility increase and decrease. Chinese researchers have also set up another mathematic model called TPB-based (Theory of Planned Behavior) and E-commerce oriented theoretical model for consumer behavior study. This model has certain constructive effects on E-commerce. But, it still has following pitfalls: (1) some variables, such as social hierarchy and culture difference, are hardly quantified; (2) the combination of qualitative simulation and quantitative one is hardly fulfilled<sup>[5]</sup>.

In china, the empirical study is seldom used in this area. The on-line investigations mainly focus on the areas such as types of users, purpose of surfing internet and comments on certain problems etc.

### 3. THEORETICAL FRAMEWORK OF EMPIRICAL STUDY ON CONSUMER BEHAVIOR IN WEB-BASED COMMERCE

There are two factors which have major impact on consumers' behavior. One is individual factors such as needs, awareness of brand identity and attitude toward brand selection. In addition, demographic factors, life style and personality have impacts on brand selection either. The other is environmental factors such as culture, sub-culture and direct contact group etc. Marketing organization also form an integral part of environmental factors. Based on these two factors, the general theoretical framework of study on consumer behavior can be set up, which is depicted in Figure 1.

Environmental and individual characteristics are known to influence emotional responses that, in turn, affect behavioral responses. In the area of environmental psychology, three key emotional variables that may determine behavior are pleasure, dominance, and arousal. These variables are also important determinants of consumer behavior off-and on-line. In a consumer context, pleasure can be defined as shopping enjoyment, and dominance as the equivalent of the perceived control felt by customers. Arousal deals with more physical sensations, such as being jittery, sluggish, or relaxed. In this study, it was not possible to directly measure physical responses to the on-line shopping experience, and instead the research concentrated on the first two variables.

**Figure 1 General Theoretical Framework of Study on Consumer Behavior**

The theoretical framework of empirical study on consumer behavior in web-based commerce, which is depicted in Figure 2, includes shopping enjoyment and perceived control as attitudinal variables that directly affect on-line consumer behavior. In accordance with

both environmental psychology and traditional consumer behavior, it also examines the direct or moderating impact of individual and Web store (environmental) factors on consumer attitudes and behavior.

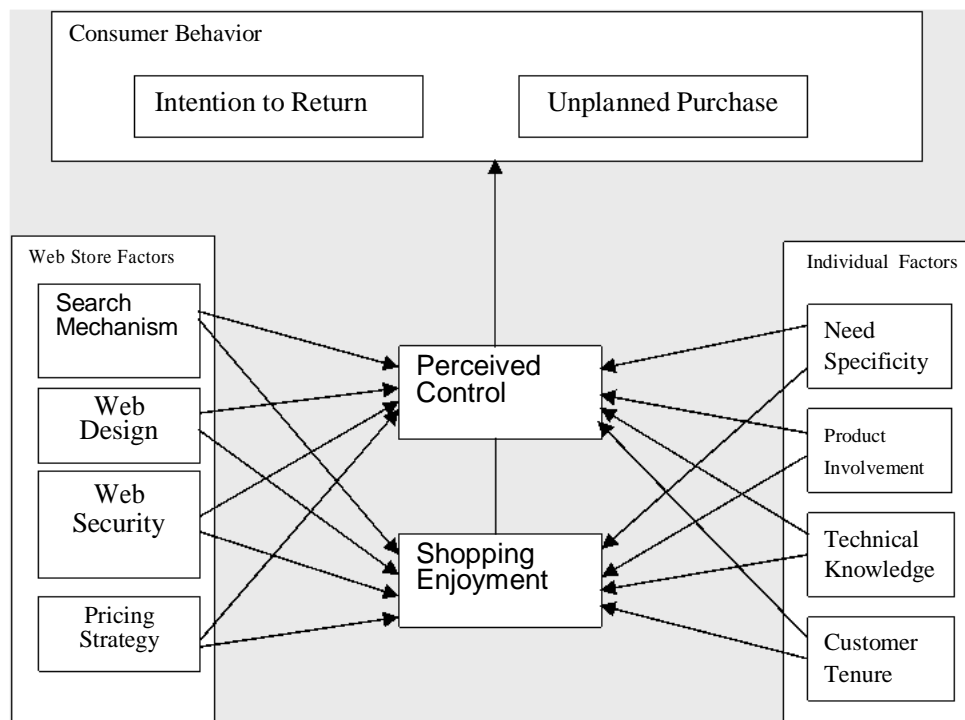

Figure 1. Theoretical Framework for Web-based Consumer Attitudes and Behavior

### 3.1 Dependent Variables

In this theoretical framework, customers' behavior is classified into two types (dependent variables). One is unplanned purchase. In some situations on the Web, conditions that enable a consumer to save time could lead to more unplanned purchases. The ability to search more products, services, and information may lead to longer purchasing decisions with a negative impact on unplanned purchases. Money availability is as important on-line as off-line. The other is customers' intention to return (repeat purchase). Repeat purchase for Web-based companies can decrease because consumers do not have to spend substantial amounts of money or time for transportation from store to store. They can buy from any company available on-line while sitting in front of their computer. Also, discretionary loyalty is no longer necessary. The center for one-stop shopping is now the customer's computer, where switching from one store to another is easy, not requiring significant physical effort, though it may require some learning of the new Web site. For consumers who dislike shopping, consumer loyalty on the Web may not decrease significantly, since even the small switching costs on the Web can prove too much for them. All of these factors suggest that the design of satisfactory experiences will be crucial to store loyalty.

### 3.2 Attitudinal Variables

Generally, the above-mentioned two kinds of consumers' behavior are affected by two attitudinal variables, i.e. perceived control and shopping enjoyment. Web stores have responded to the desire for customer control and convenience with systems that enable

consumers to easily find what they need, learn more about it, and quickly make a purchase decision. Internal search engines, hierarchical classifications of company products, and intelligent agents are provided by many Web stores to support users' need for control in accessing information. Sites offer quick, automated purchasing through "one-click" buying and the use of shopping carts. All these site features enable Web customers to enjoy higher levels of control and convenience. Shopping on-line is a different experience from shopping in a physical retail store. One major point of difference deals with "store atmosphere". This term describes the physical aspects of a store, such as colors, music type, music volume and tempo, and layout of products. Store atmospherics have a direct effect on customer mood and behavior. The atmosphere of Web-based businesses is at best limited to the confines of a computer monitor that usually displays only two-dimensional pictures and text. Even with the addition of three-dimensional images and musical accompaniment, Web stores today cannot fully simulate the ambiance of a physical store. In the competition between click and mortar, the system design of the e-tailing experience must compensate for the loss of traditional in-store atmosphere.

### 3.3 Individual and Web Store Factors

Obviously, the attitudinal variables are affected by individual and web store factors. Individual factors include the following sub-factors: (1) Need Specificity: in other words, how well individual consumers know what they want when they visit a store; (2) Product Involvement: the concept comprises (a) one's motivational state (i.e., arousal, interest, drive) toward

an object where (b) that motivational state is activated by the relevance or importance of the object<sup>[6]</sup>; (3) Technical Knowledge: how well individual consumers know what kind of skills they need to surf internet smoothly; (4) Customer Tenure: how many times a customer has been to a Web store in the past. Web store factors include the following sub-factors: (1) Search Mechanism: i.e. site search features, such as internal search engines, hierarchical classifications, and intelligent agents etc.; (2) Web Design: attractiveness of web site; (3) Web Security: the safety of flow of information, cash and goods etc.; (4) Pricing Strategies, such as discount pricing strategy, reputation pricing strategy and personalized pricing strategy etc.

#### 4. CONCLUSIONS AND DIRECTION OF FURTHER RESEARCH

Based on general theoretical framework of study on consumer behavior and current achievement in this area both oversea and home, the theoretical framework of empirical study on consumer behavior in web-based commerce is put forth. In this theoretical framework, two dependent variables is determined as unplanned purchase and customers' intention to return, which are affected by two attitudinal variables, i.e. perceived control and shopping enjoyment. The two attitudinal variables are also affected by individual factors and web store factors, which also contain certain sub-factors.

Through this theoretical framework, the factors that influence customers' on-line behavior can be determined. However, the influence rate of each and every factor still remains unclear. To solve this problem, the empirical study based on this theoretical framework should be adopted. One of the best methods of empirical study is by on-line questionnaire. Through questionnaire and with the help of statistical software, the significance of each factor can be measured by regression analysis.

Modern technology equips consumers by giving them accessibility to unprecedented information and communications. As customers' switching costs goes down, the challenges of attracting, retaining, and realizing profits from customer interactions increase. Well-conceived studies that integrate marketing perspectives on consumer behavior and information systems research on users' behaviors will be crucial to

understanding consumers' on-line behaviors. Indeed, each of the major variable categories considered in this theoretical framework, i.e. individual consumer factors, Web site design factors, consumer/user attitudes and decision processes, and behavior, presents opportunities for marketing and information systems researchers. Further research on these topics from a multidisciplinary perspective will be critical to the effective design of systems that strategically influence customer behavior.

# Willingness to Pay for Digital Services: Challenges for Future Research

Herbjorn Nysveen<sup>1</sup>, Per E. Pedersen<sup>2</sup>

<sup>1</sup>Norwegian School of Economics and Business Administration

<sup>2</sup>Per E. Pedersen, Agder University College

## ABSTRACT

In this article we discuss three issues that should be considered important in future studies of willingness to pay (WTP) for services in digital networks. First, existing studies of WTP for digital services have several weaknesses when it comes to context- and incentive realism and we suggest alternative methods to overcome these weaknesses. Second, a review of existing studies of WTP for digital services also reveal that existing studies are narrowly focused on measures of willingness to pay. Thus, a nomological network of WTP is suggested to get a broader theoretical framework for purposes of validation of pure willingness to pay measures. Finally, existing studies on WTP for digital services has focused single-channel services. The large number of cross-channel and multi-channel services offered in digital networks, makes us point to the importance of WTP studies for cross-channel and multi-channel digital services in the future.

## 1 INTRODUCTION

Consumers' spending on online content has increased significantly from 2001 to 2003 (Online Publishers Associations, 2002). A brief review of studies of WTP for digital network services shows that studies are conducted on WTP for broadband enabled services on the Internet available through computers (Sage Research, 2002; eBrain, 2002; Jupiter Research, 2003; Online Publishers Association, 2002; Makarem, 2001), digital services available through high definition television (HDTV) (The Leichtman Group, 2003), and mobile services (Coleago Consulting, 2002; Nokia, 2001; Ericsson, 2002; Forbes, 2003). In this article, the summary of the main findings for mobile services is based on a limited number of empirical studies. However, for 3G mobile services, entertainment services seem to have a high potential (Nokia, 2001), although there are some interest reported also for utility services as news delivery (Forbes 2003) and travel information (Driscoll and Associates, 2003). Also, for general broadband enabled services, several studies indicate that entertainment services are among the services with the largest market potential (Sage Research, 2002; Lyra Research, 2001; Online Publishers Association, 2002). Within this category, movies on demand (Sage Research, 2002; Myrio, 2003), concerts and cultural events (Sage Reserach, 2002), TV shows on demand (Sage Research, 2002; Myrio, 2003), and music download (Sage Research (2002) seem to be the services customers are willing to pay most for. For digital services, studies have focused age (Coleago Consulting, 2001; Myrio, 2003), probability of adoption (Colleago Consulting, 2001), stage of adoption (Nokia, 2001), uniqueness of service (Anstine, 2001; Edison Media Research, 2002), access to broadband (Jupiter Research, 2003), convenience (Molteni and Ordanini, 2003), and whether copies and file transferring is allowed (eBrain, 2002; Jupiter Research, 2003) as variables moderating customers' willingness to pay.

## 2 PURPOSE OF THE ARTICLE

Studies on WTP for services in digital networks have three typical characteristics. First, the methodology used to measure willingness to pay is typically based on surveys where the respondents hypothetically are asked how much they are willing to pay for a specified service (Coleago Consulting, 2001; Sage Research, 2002; Makarem, 2001; Leichtman Research Group, 2002). This means that the studies are not conducted in a real purchase situation, and the respondents are not given any specific incentives for revealing their true willingness to pay. This method has often been criticized for overestimating consumers' willingness to pay (Botelho and Pinto, 2002; Wertenbroch and Skiera, 2002). The first purpose of this article is therefore to discuss the importance of studying consumers' WTP for digital services in a more realistic context and with more realistic incentives.

Second, existing studies only marginally discuss willingness to pay as a theoretical construct (Ericsson, 2002; eBrain, 2002; Makarem, 2001; Edison Media Research, 2002; Nokia, 2001; Coleago Consulting, 2001; Leichtman Research Group, 2002). It is argued by Wertenbroch and Skiera (2002), that when using the survey method, application of a variety of willingness to pay measurement procedures should be used for cross validation purposes. Thus, supplementary theoretical perspectives from the nomological network of willingness to pay should be included to evaluate measures of consumers' willingness to pay for services in digital networks. Although some variables are revealed to moderate consumers willingness to pay for digital services, several other variables revealed to influence consumer behavior in general also seem to be relevant to include. Thus, the second purpose of the article is to highlight the importance of a broader theoretical manifold in WTP studies and to present a nomological network of WTP, including a discussion of potential moderating variables.

Third, the studies typically measure customers' willingness to pay for single-channel services (Sage Research, 2002; Makarem, 2001; Myrio, 2003). Often, a brand or a company is offering a service through more than one channel. However, we have not been able to find studies focusing willingness to pay for content in a multi-channel/cross-channel service compared to a single-channel service. Consequently, the third purpose of the article is to address the importance of focusing willingness to pay for cross-channel and multi-channel digital services.

### 2.1 Purpose 1: Context and incentives when studying willingness to pay

Four methods to estimate willingness to pay are described by Wertenbroch and Skiera (2002). The methods differ in their incentives to reveal true willingness to pay and simulation of actual point of purchase context. With the transaction method, respondents receive a fee before the estimation of WTP begins. They are then exposed to products where the price is manipulated, and they chose to buy the product with the manipulated price they perceive as "right". The method can be pure experimental or it can take place in a real purchase situation. The fee given to the respondents reduce the possibility that estimates are biased downward due to liquidity constraints. Thus, incentive compatibility should be considered relatively good when using the transaction method. By using the transaction method, only the pure experimental approach will be useful for revealing willingness to pay for products and services yet not on the market. However, in pure experimental studies, simulation of actual point of purchase context suffers, and the revealed willingness to pay may be biased.

One of the survey methods discussed by Wertenbroch and Skiera (2002) is based on contingent valuation of customers' WTP for a given product. This method could be used by an open ended approach, where customers are asked to state their WTP for a given product, or by a close-ended approach, where customers' choose whether to buy a product at given price alternatives or not. When using the contingent valuation method respondents are typically given a description of the product/service evaluated and the hypothetical circumstances under which it is made available. Thus, the WTP estimated by the respondents do not have any implications for the respondents, and the context is hypothetical. The survey method, therefore, scores relatively low both on incentives to reveal true WTP and on simulation of actual context.

The Vickrey auction (Wertenbroch and Skiera, 2002) is a sealed-bid auction. The incentive compatibility in this method is relatively good, because the respondent with the highest bid must buy the product. Thus, the WTP estimated by the respondents have implications for the respondents. However, there is a limited stock of products, so respondents compete with one another to

win the auction. The stock constraint used in Vicroys method contrasts the usually unrestricted supply of products in a real retail setting. The method is experimentally, and respondents meet and make decisions regarding willingness to pay in a research facility. Thus, simulation of actual point of purchase suffers when using the Vickrey auction method.

With the Becker, DeGroot, and Marschak's (BDM) (Wertenbroch and Skiera, 2002) method, respondents are told that the price of the given product is not yet set, and that we (the researchers) want to know the highest price the respondent is willing to pay for the product. When the respondent has reported his final WTP, he draws a price from an urn. This price will be the actual transaction price. Thus the actual transaction price is set randomly, and the actual transaction price is exogenous to respondents WTP. If the price is less or equal his WTP the respondents are offered the opportunity to buy the product for the price drawn from the urn (which is equal or lower than his WTP). If the price he draws is higher than his WTP, he will not be able to buy the product. The method is also based on "out-of-pocket transactions". Thus, the WTP estimated by the respondents has some implications for the respondents. By using BDM, customers' willingness to pay can be estimated at the point of purchase and thus vary according to purchasing context and competitive set. This possibility ensures point of purchase realism when using the BDM-method.

**Table 1:** Characteristics of the four methods.

Method	Incentive compatibility	Point-of-purchase realism
Transaction method	Good	Bad
Survey method	Bad	Bad
Vickrey auction method	Good	Bad
BDM method	Good	Good

The overview given in the table are somewhat simplified due to the fact that there are versions of the four methods described. For example, point of purchase realism for the transaction method depends on whether it is a pure experimental approach or a quasi-experimental approach.

The review of WTP studies for digital services shows that most of the studies are based on the survey method with a contingent valuation approach. Several studies have revealed that the use of the contingent valuation model overestimate customers' willingness to pay compared to customers' real willingness to pay (Botelho and Pinto, 2002; Wertenbroch and Siera, 2002).

### 2.2 Purpose 2: Nomological network of willingness to pay

Below we briefly review a few other theoretical perspectives related to WTP in order to establish the nomological network of willingness to pay.

### 2.2.1 Acceptance and adoption

In information systems research, two constructs are closely related to willingness to pay - adoption and acceptance. Three models stand out as the most widely applied to explain information systems and service adoption intentions. The technology acceptance model (TAM) (Davis, 1989) focuses on the cognitive and affective explanations of intention to use a specific technology or service. It includes five concepts - perceived user friendliness, perceived usefulness, attitudes towards use, intention to use and actual use. TAM may be seen as a special case of the TRA - theory of reasoned action (Fishbein and Ajzen, 1975). TRA includes four general concepts - behavioral attitudes, subjective norm, intention to use and actual use. In general TRA does not propose specific determinants of behavioral attitudes (attitudes towards use). However, in TRA these attitudes are composed of the belief that use leads to certain outcomes, and the evaluation of the desirability of these outcomes. The inclusion of subjective norm, however, represents an important additional social explanation when compared to TAM. The theory of planned behavior (TPB) was proposed as an extension of the theory of reasoned action to account for conditions where individuals do not have complete control over their behavior (Ajzen, 1991). This is particularly relevant to situations of service adoption under financial or other behavioral constraints. Perceived behavioral control - as included in TPB - reflects the internal and external constraints on behavior, and is directly related to both behavioral intention to use and actual use (Ajzen, 1991).

### 2.2.2 Marketing and consumer psychology research

Constructs positively related to customers' willingness to pay in marketing and consumers' psychology is awareness, attitude, intention, and choice. Awareness reflects customers' awareness, their interest level, or their readiness for a service or a product (Schiffman and Kanuk, 1997). Peoples' consciousness, or awareness, about an object is found to influence customers' willingness to pay for the object positively (Vlosky, Ozanne and Fontenot, 1999). When it comes to attitude and intentions, theories as theory of reasoned action and theory of planned behaviour are also used in marketing. Attitudes and intentions are assumed to influence actual choice positively. Positive effects of attitude toward an object on willingness to pay for the object are revealed by e.g. Rio, Vazquez and Iglesias (2001).

### 2.2.3 Moderating variables

In the review of studies focusing WTP for digital services we reported several variables revealed to influence customers WTP for digital services. However, what is absent in this research is traditional moderating variables found to be of importance for customers behavior in many studies; such as consumers' channel

experience (Bruner and Kumar, 2000), product knowledge (Bei and Widdows, 1999), product expertise (Alba and Hutchinson, 1987), perceived risk (Dowling and Staelin, 1994), and product involvement (Bei and Widdows, 1999).

The nomological network is illustrated in figure 1.

By including several variables from the nomological network of WTP, measures of WTP can be validated against other measures related to WTP. Furthermore, as can be seen from figure 1, the variables included in the nomological network can be seen as a causal flow of psychological processes starting with product awareness, mediated by cognitive, affective, and conative mental processes, ending with a perception of WTP and a decision (choice) to buy/adopt the product/service or not. Thus, the variables included in the nomological network of WTP may also be used to explain the psychology behind the observed WTP.

### 2.3 Purpose 3: Willingness to pay for cross-channel and multi-channel services

Cross-channel services refer to services with identical content distributed in two or more channels. Multi-channel services are defined as services with supplementary or complementary content in additional channels. An example of a cross-channels service is when television companies give customers the possibility to watch television programs on their computer through the Internet at the same time as it is broadcasted on television. However, it is a multi-channel service when customers are given the opportunity to use their mobile phones to vote or make comments when watching a television show.

What is interesting in such a services context is whether access to content in a new channel has an influence on customers' willingness to pay for content in existing channels. One way to shed some light on the importance of this is to relate the discussion to whether cross-channel and multi-channel services are substitutes, supplements or complements to each other. If people start to watch television shows on their computers through the Internet instead of watching on television, this is an example of channel substitution. If additional content related to a television show is offered through SMS or MMS without any changes in people watching the original show on television, this is an example of supplementary services. However, if these subscription services on SMS and MMS increase the interest in the television show, the additional channels are complementary to the original channel. In particular in

situations characterized by supplementary and complementary channels, willingness to pay becomes more complicated. When channels are supplementary (see e.g. Riel, Liljander and Jurriens, 2001), people are using a new channel in addition to the original channel to get access to the service. This does not influence their interest or use of the original channel, meaning that only the use of the new channel represents an increased interest or use of the service. Given that the new channel used is not free, this represents an increased willingness to pay for the service. In a complementary situation (Dutta-Bergman, 2004), the content offered in one channel influence the interest and use of content available in other channels. Thus, we have a situation characterized by channel synergies where perceived value of the content presented in one channel increase as a result of the additional content of the service offered in another channel. This increased value means people will be willing to pay more for the content distributed in the original channel in addition to their willingness to pay for the content distributed in the additional channel.

### 3 PROPOSITIONS FOR FUTURE RESEARCH

#### 3.1 Context and incentives when studying willingness to pay

The measures of customers' willingness to pay for digital services are, due to the heavily use of surveys methods (contingent valuation approach), probably not very precise. Thus, an important issue in future research should be to develop more accurate methods to measure customers' willingness to pay for digital entertainment services. In particular, we have pointed to the importance of more realism in incentives and point of purchase context, as discussed by Wertenbroch and Skiera (2002). Thus, a main issue we suggest should be focused in future studies of WTP for services in digital networks is:

Future research 1: to deploy methods that includes more realism in incentives and point of purchase context.

#### 3.2 Nomological network of willingness to pay

Most of the research on WTP for digital services is only marginally based on theoretical discussions and reflections. The ones who are have focused relatively narrowly on the WTP construct. One way to overcome this weakness is to build on the nomological network of willingness to pay. By doing this, measures from various theoretical perspectives can be used, and the results revealed from the various theoretical perspectives can be validated against each other – giving us more trustworthy results of customers' willingness to pay for-, accept-, adopt-, use-, etc. digital entertainment services. Therefore, one of the issues that should be focused in future research on customers' willingness to pay for digital entertainment services is:

Future research 2a: to deploy of a broader spectre of

methods and measures to reveal what we believe will be a more correct estimate of customers' willingness to pay for digital services.

In addition, the inclusion of variables in the nomological network of WTP makes it possible to explain the causality between variables in the nomological network of WTP - increasing our understanding of how to influence consumers' WTP. Future research should therefore;

Future research 2b: study the causality between variables in the nomological network of WTP.

The discussion presented in this article also reveals that relevant moderating variables found to influence consumers' behaviour in general are not included in studies of customers' WTP for digital services.

Future research 2c: Effects of potential moderating variables should therefore be included in future studies to get a more nuanced picture of willingness to pay for digital services in various customer segments.

#### 3.3 Willingness to pay for cross-channel and multi-channel services

None of the reviewed studies of willingness to pay for digital services focus on willingness to pay for cross-channel services or multi-channel services. Several digital services are available in more than one channel. Thus, it will be of interest to study changes in willingness to pay for digital services in the main channel when the digital services are presented in additional channels as well. We therefore suggest that future research should;

Future research 3: study customers' willingness to pay for not only singles channel services but also cross-channel services and multi-channel services.

## ABSTRACT

On the basis of analyzing customer services of manufacturing enterprises and these supporting requires, using the method of discrete system simulating, the paper provides the classifications of customer services suitable information technology supporting, brings forward the working mechanisms suitable to the supporting system of different kinds of customer services and the relevant system structure.

**Keywords:** customer service (CS), customer service support system (CSSS), working mechanism, system structure

## 1. INTRODUCTION

To manufacturing company, with the fierceness of the market competition, customer service of enterprise faces all kinds of presses such as the increase of working load, serve standard raising, resource limited and fund shortage,<sup>[1]</sup> and customer service bears dynamics, complexity, timeliness and outburst of time and space, so enterprise requires customer service supported by information technology which can be realized with low cost, effective resource allocation and fast and automatic reactivity. The domestic and international relevant scholars have studied in regarding customer service and its supporting technologies with information technology<sup>[2-9]</sup>, the typical applications include mainly: customer care, dispute disposing, order following, field service, and database of problem and solution, etc. Many kinds of new methods of customer service such as Web, VoIP, Email, Live Chat, Virtual Reps have appeared. But the applications of the technology are mainly the support to the concrete business of customer service and have supported the development of enterprise's customer service to a certain extent, but set foot in little in decision of enterprises service resource scheduling. The problems such as rational arrangement and managing enterprises service resources, integrating the numerous service methods and formulation of the service tactics are that enterprises are badly in need of solution at present. Though customer service has many kinds of different classification already,<sup>[10,11]</sup> it can't totally respond to the request of customer service supporting with information technology yet. So it is very necessary to study the classification of customer service in more pertinence, which can help to provide different and more effective disposing mechanisms for all kinds of customer services.

Customer service supporting system is a part of customer relationship management system backstage supporter their system, supports and restricts whole customer relationship construction and service support operation, and plays a key role in the system, so its working mechanism and system structure become hotspot in theory and practice to study. Systematic simulation has already been applied to numerous

systems such as economic system, business system, and logistics management system extensively. By the look of resource competition, customer service is a kind of question of lining up, and dispersed incident systematic simulation is a kind of auxiliary administrative skill and can preferably solve this problem<sup>[12,13]</sup>. Because of the characteristics of customer services, the study of customer service not only focuses on simulating experiences and suitable service strategies, also includes the customer service support system that integrates the testing study and practicing support.

Taking manufacturing enterprise as the background, this paper provides a kind of new customer service classification based on discussing influence factors of customer service, designs system model of event-driven customer service using systematic simulation technology, provides system structure and the corresponding systematic module to provide guidance for development of enterprise's customer service, distribute the service resources of enterprises rationally in the course of implementing and improve the customer satisfaction of enterprises.

## 2. CUSTOMER SERVICE CLASSIFICATION SUITABLE TO CSSS

The customer service is a very extensive concept, does not confine to narrowly-defined ranges such as traditional selling service and after-sale service and should include these activities, such as advertisement, free trial, presentation and investigation, solicitude and support to customers which get in touch with enterprise, involving the whole cycle of selling products. So the customer service is not only the service request responding the customer passively briefly, should also offer customer service voluntarily.

### 2.1 Influencing Factors of Customer Service

The service time variable not only points the implementation time of the customer service but also includes the makeup-time and latency time of service. As latency time correlates with the customer service tactics of enterprises and customer service resource and

does not have direct relation with customer service, only implementation time and make-up-time of the customer service are considered here. In the customer services that enterprises offer, some are finished once, otherwise, some are implemented many times stage by stage, where the service time of this kind of customer service is made up of implementation time of a lot of customer services. So service time  $T$  can be described as following:

$$T = f_1(n), \quad (1)$$

where  $n$  denotes stage degree of service. When  $n$  is equal to one,  $T$  is short, and  $T$  is long when  $n$  is bigger than one.

Service costs include only labour cost  $l$ , material cost  $m$  and opportunity cost. Labour cost depends on the service provider and shows significant degree of customer attendants in enterprises. The material cost is the value of the corresponding material while offering this kind of customer service by enterprises, if maintaining the three guarantees products, enterprises should offer the corresponding spare part to replace the trouble one. When a certain customer service needs to consume material cost, not only raise the service costs of enterprises, may take more makeup-time for planning the material. The opportunity cost means possible losses caused by that enterprises appoints competent technology and management attendants to implement one requiring the low customer service to engineering level. Because the attendants with competent technology are limited in quantity, so this kind of chance loss may cause another customer service expected much to engineering level not to get prompt treatment. So service costs can be described as the following:

$$C = f_2(l, m), \quad (2)$$

where  $l$  is low without  $m$ ,  $C$  is low, and  $C$  is high when  $l$  is high or there is  $m$ .

Different customers have different customers' value to enterprises. If enterprises do not distinguish the customer according to these value, it will cause that some customers' actual contribution to enterprise are still not enough to remedy the input of enterprises for them, otherwise, some customers are influenced as investment to them is insufficient. According to customer value, all the customers can be classified into important customers and ordinary customers shown by  $G$ . There are present customers in the important customers, and there are potential customers too. The important customer enjoys enterprise's customized customer service, and enterprises offer ordinary customer service for ordinary customer.

## 2.2 Classification of Customer services

Considering above-mentioned influence factors synthetically, customer service classification  $Y$  can be

defined as follows:

$$Y = f_3(T, C, G) \quad (3)$$

The customer services of manufacturing enterprises can be divided into event type, activity type and process type three kinds, according to  $T, C, G$ , and the requires, feasibility and simplicity realized of information supporting technologies to customer services, showing as table 1.

Table 1 Value of Customer Service Classification

$Y$	$T$	$C$	$G$
Event Type	Short	Low	Ordinary
Activity Type	-	High	Ordinary
Activity Type	Long	Low	Ordinary
Process Type	-	-	Important

Event type customer service is a kind of customer service that possesses of short service time, low service cost and ordinary customer, which is one stage service. The realization of event type customer service can be regarded as the array of event serials made up of beginning event and ending event.

Activity type customer service is a kind of customer service that possesses of long service time or high service cost and ordinary customer, which is multi-stages service, and the beginning of subsequent service decides by the foregoing service. Activity type customer service accords with the definition of activity in activity scan simulation method, so it can be disposed as an activity.

Process type customer service has nothing with two factors of service time and service cost, only decided by customer types, whose customer is important customer. It is not a certain concrete customer service, but a kind of customer service tactics of enterprises, it covers the customer's whole life cycle and is a service package including lots of services for the important customers. Each service package is different from others as each of them faces a certain important customer. So process type customer service is made up of event type customer services and activity type customer services disposed as event and activity respectively. A process type customer service including these events and activities is disposed as a process.

Three kinds of customer services have different service costs, among them the incident type has the lowest customer service, the course type is the highest, the differentiation of this kind of service cost contributes to controlling enterprise's service cost, and the enterprise can provide different customer services to different customers discriminatively. The serving objects of three kinds of customer services are different, those of the event type customer service and activity type customer service are ordinary customers, those of process type

customer service is important customers, which contributes to guaranteeing enterprise's main profit source and satisfies the service of the important customer. From the point of information technical support, above-mentioned categorized methods can help enterprises to implement customer's service support system based on information technology better.

### 3. WORKING MECHANISMS OF CSSS

Systematic simulation is a course of solving the dynamic system model with number value method, which understands and predicts systematic behavior through the experiment of a realistic system or the system model that plans to be set up. Event step method in dispersed incident systematic simulation is often used to simulate enterprise management system, which is divided into three kinds of different simulation working mechanism: event-driven method, activity-scanned method and process-switched method.

#### 3.1 Working Mechanisms of CSSS used by Event-driven Method

Event-driven method is described in Ref. 12 as: Operations of system are made up by a series of emergence of events according to time, courses that take place inside are regarded one array of events and future event list (FEL) is adopted to confirm the order of events according to each time that events happen. The incident of time take place first is chosen from FEL, each time the most necessitous event is disposed, simulation clock is advanced to here incident time at the same time, then the corresponding event subprogram is carried out, the corresponding systematic state of changes, and any condition is tested and happened in the incident subprogram. After an event is dealt with, it retreats from FEL. The operation of the event-driven simulation method includes two stages: (1) Time scanning, to carry out two operations: scanning future incident form FEL to confirm next time that event happens, and moving e forward clock to present time. (2) Event execution, to transfer the corresponding event subprogram. Carry out two these repeatedly, until the fact that fixed simulation end conditions are satisfied.

In three kinds of customer services, the event type customer service is made up of service beginning event and service ending event, and the emergence course of it also composes of the array of these two events above. The activity type customer service can be regarded as a lot of associations of event type customer services, it also composes of service beginning event and service ending event too, but a different one is that the end of anterior events can touch off the beginning of the next stage. The process type customer service is the service package made up of event type customer services and activity type customer services. So Event-driven method can be adopted to support tactics and simulation implement of the three kinds of customer service above.

#### 3.2 Working Mechanisms of CSSS used by Activity-Scanned Method

Activity-scanned method is the simulating method based on activity scanning. Beginning events and ending events of are initialized by terms that the activity stipulate, and not prearranged by the model. In three customer services, event type customer service does not adapt to activity-scanned method because it is one stage service. Activity type customer service is made up of lots of stages where subsequent service is decided by anterior service, so it is suitable to activity-scanned method. Process type customer service includes activity type customer services, so it can be disposed using activity-scanned method.

#### 3.3 Working Mechanisms of CSSS used by Process-switched Method

Process-switched method is the simulating method based on processes that compose of the array of events and some activities. Event type customer services and activity type customer services are unsuitable to process-switched method because of their characteristics. Process type customer service is made up of event type customer services and activity type customer services, so it can be disposed using activity-scanned method.

Fig. 1 Working Mechanisms suitable to each kind of CS

Fig.1 shows the different working mechanisms supporting the three kinds of customer services in customer service support system.

### 4. STRUCTURE AND REALIZATIONS OF CSSS

#### 4.1 Main Data Structures of CSSS

The static information of system consists of customer information, customer service information, the detail of activity type customer service, the detail of process type customer service, distant time weight, distance weight, balanceable guideline weight, service attendants' information and city geographical information. Here, customer information is the relative information to customer weight, and not customer dossier in customer relationship management. Customer service information records all the services developed by the enterprise. The detail of activity type customer service records the information of each stage services in activity type customer service. The detail of process type customer

service records all the service items of important customers served in process type customer service, which includes the following word sections: customer number, product number, service number and prospective service time, where prospective service time denotes prospective time of each service item. Distant time weight records every weight that increases after certain time interval to count. Distance weight records every weight that increases after certain distance interval to count. Balanceable guideline weight records the weight in total PRI of each index. Service attendants' information records the personal information and technology level information of all the attendants. City geographical information records the longitude and latitude of all over the national cities, and the grain size reaches the county.

The dynamic information of system consists of the information in the following tables: present event list, future event list and customer latency time list. Present event list records present customer services serving, future event list records waiting customer record having been in service queue, and customer latency time list records the latency time taking in each serving.

Service tactics storehouse mainly records service tactics used by the enterprise and their purposes. In system, service tactics represents as variation of all the weights, and their purposes are mainly evaluated by the average of latency time. In service tactics storehouse, there are three kinds of average of latency time: the average of latency time of important customers, the average of latency time of ordinary customers and the average of latency time of all the customers, which are used to judge the influence of service tactics on the important customers, ordinary customers and the whole customer cluster of the enterprise. These information in service tactics storehouse not only are an evaluation to former service tactics, also use for reference to drawing new service tactics.

There are three kinds of events: happening event of new service need, service ending event and latest approaching clock event, to vary the systematic state. Happening event of new service need denotes the new service need being from customers or new customer service practiced by the enterprise, whose direct influence is to add new record in FEL. Service ending event denotes that the serving customer service has completed, whose direct influence is this record of customer service will be deleted from FEL. Because not all the waiting service records need to be served immediately, the latest approaching clock event is set to dispose them. When latest approaching clock event is touched off, system transfers directly the calculating rules of entering FEL, inserts suitable record into FEL and make it be served.

#### 4.2 Function and Structure of Event-driven CSSS

Customer service support system is one of the back platform subsystems of customer relationship management system. It supports customer service and the practice of customer service, makes it be the profits center by distributing customer service resources and decreasing costs. Because of the concrete difference in business treatment of customer service, as an event-driven customer service system in common use, it does not participate in the actual treatment of enterprise's customer's service items, but regarded as a middle bridge between customer identifying system and enterprise's customer service process system. The event-driven customer service system receives service needs of customers issued by the intellectual agent's system of the customer service, optimizes these needs, distributes the service resources of enterprise in reason, and submits them to enterprise's customer's service item process system. So its main function is the support to decision-making and practices. Fig. 2 shows the information flows of customer service support system, and Fig. 3 describes the structure of the system.

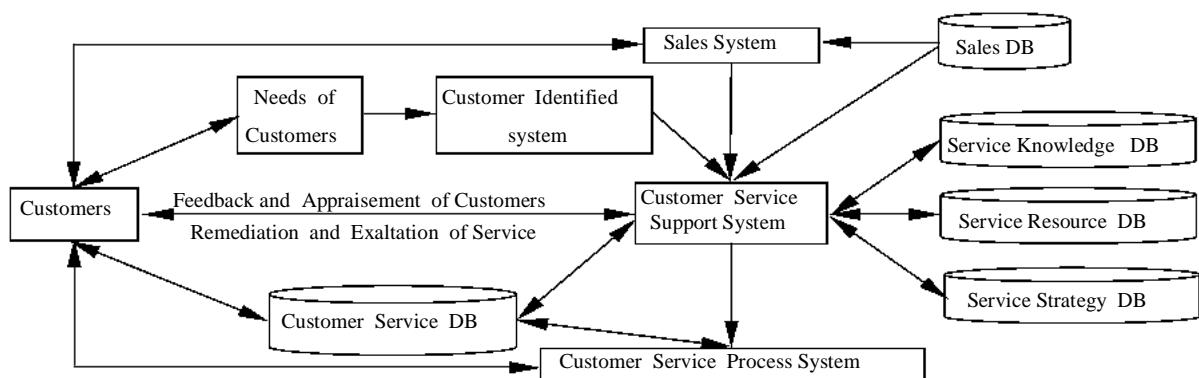

Fig. 2 Information Flows of Customer Service Support System

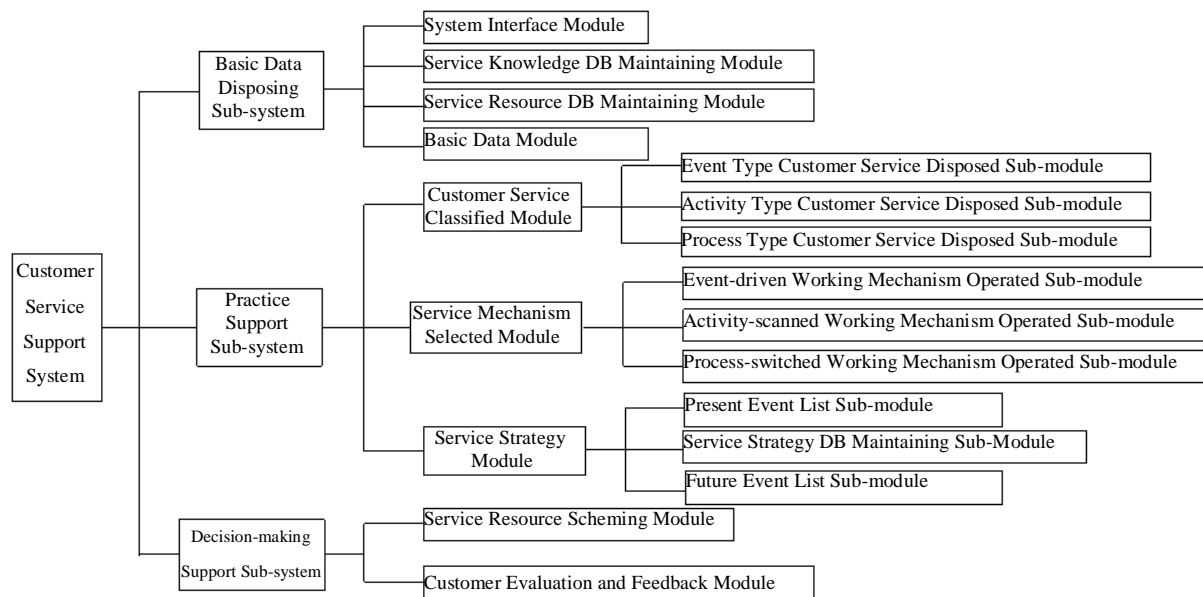

Fig. 3 Structure of Customer Service Support system

#### 4.3 Realization of Event-driven Working Mechanism

Event-customer service is not a concrete customer service, it is a kind of customer service with the same working mechanism, though the service content of each kind of customer service has very great differences, they possess the characteristics of event-customer service such as the short service time, low service costs and general customers, so their way of taking up enterprises service resources is the same. The event type customer services accords with the so-called a M / G / 1 system<sup>[14]</sup> <sup>[15]</sup> <sup>[16]</sup>, namely a queuing model where the flows of customer reaching are the simplest flows, service time is at random and it possess one information desk. So the realization course of customer service A can be simulated using M / G / 1 system.

The simulative models of event-driven method include defining entity and entity set, defining activity and event, and describing event disposal. Here, the entities compose of a lot of customers and an information desk, the entity set is customer queue, the activities include waiting, being served and falling out the queue, the events compose of reaching information desk named event 1 and going away from information desk named event 2. The disposing procedures of event 1 and event 2 can refer the relative reference. Fig.4 describes the disposing procedure of event-driven working mechanism for event-customer service.

The simulating model of activity-customer service is similar with that of event type customer service except that the customer is served by service  $B_1$  and service  $B_2$  in turn in activity type customer service. We can suppose that customers arrive at  $t_1, t_2, \dots, t_n, \dots, t_{n+m}, \dots$ , where we can think that a customer is served by service  $B_1$  at  $t_n$  and by service  $B_2$  at  $t_{n+m}$ , the service times are independent and the twice arrives of a customer are

thought as the arrives of two customers. The flows of customers reaching are the simplest flows, so activity type customer services can also be simulated using M / G / 1 system. There are three kinds of events: reaching information desk named event 1, producing condition after service  $B_1$  named event 2 and going away from information desk named event 3, where the disposing procedure of event 1 and event 3 is similar with those of event-customer service, and other disposing procedures are omitted limit to space.

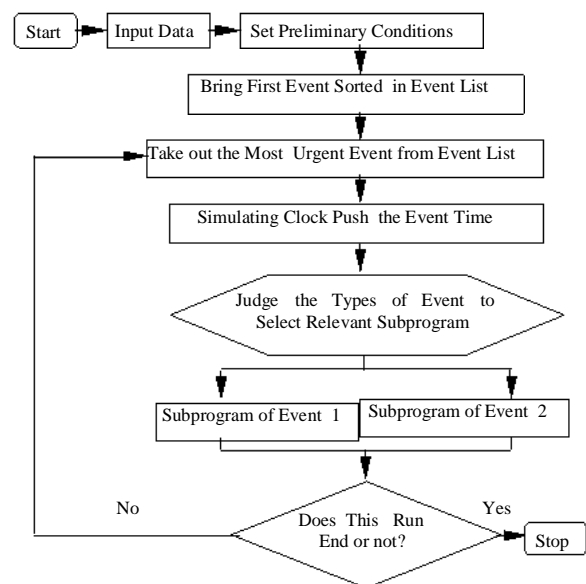

Fig. 4 Procedure of Event-driven Working Mechanism for Event-customer Service

Because the process-customer service is a service package made up of event type customer services A and activity-customer services B, we can adopt the procedures of event type customer service and activity-customer service in simulation of process-customer service, whose simulating model and

events are made up of the models and events of event type customer services and activity type customer services. The relative models and disposing procedures are also omitted.

## 5. CONCLUSION

According to the three variables: service time, service cost and customer type, this paper provides the three types of customer services: event type customer service, activity type customer service and process type customer service. Simulating the procedures of these customer services using event-driven method and establishing the system structure of customer service support system, which help enterprises to optimize the procedure of customer service, raise the efficiency, lower costs, reduce service accident, and this customer service support system model has oneself ability of appraising and adjustment.

Of course, this paper has laid particular emphasis on studying event-driven working mechanism, and there is the research to activity-scanned working mechanism and process-switched working mechanism remaining to continue carrying on deeply. At the same time because different working mechanism have different influence on way and result in which the customer service is implemented, it is necessary to compare the result of adopting different working mechanism of three kinds of customer services, find out the most suitable working mechanism of each kind of customer service, then set up system in common use. As regards technological aspect, information technology adopted in different working mechanism need to study further. At aspect that system implement, customer service support system and other data of system share also await to study and discuss.

### ABSTRACT

Simulations preserve the knowledge of complex dynamic systems and consequently transfer the knowledge of the cohesions of its elements to a specified target group. As the progress in information technology and therefore the dynamic e-business driven economy adapts even faster to the business demands, new ways to preserve this growing amount of knowledge have to be found. This paper presents an extensible business simulation framework which is realized as a component-based distributed Java Version 2 Enterprise Edition (J2EE) architecture. The framework aspires to offer an extensible and domain independent simulation environment which ensures the return of investment in the sense of implementing this framework once and extending it to the future requirements of diverse domains in e-business. The system architecture follows the requirements in offering distributed deployment of its components on highly standardized level by nevertheless staying vendor independent. The architecture itself was developed by model driven architecture (MDA)-conform software engineering methods using best of breed design patterns composed to a flexible micro-architecture which possess import facilities for simulation entities (business objects) and (business) processes from e-business solutions. Combining the features of the framework, the layered pattern driven micro-architecture, and the distributed J2EE architecture, the postulated knowledge transfer from rapid changes in e-business can be realized.

**Keywords:** business simulation, framework, architecture, J2EE, e-learning, e-business

### 1. INTRODUCTION

Business simulations play a major topic in industry and higher education for more than 40 years. They preserve the knowledge of complex dynamic systems by modeling the cohesions and dependencies between the simulations' objects and transfer the modeled information by simulating its dynamic aspect on computer systems [1, 18]. In that way the knowledge about the behavior of the dynamic system is transferred to the specified target group [21]. Depending on what knowledge should be preserved, the cohesions of the system for the audience the simulation may differ. These advantages were identified by the American Management Association by developing its Top Management Decision Simulation in 1957. From 1957 till 1962, 89 different business simulations were developed by the industry, universities and other organizations [24]. In 1965 an accounting and book keeping simulation was developed to show the dynamic dependencies between the related records. Four types of simulation models were identified: strategic planning, internal planning, training program and research [19]. As a lack of computer systems these days, simulations were limited to non-executable implementations without having the ability to vary its modeled cohesions. As computer systems grew to solve more and more automated processes the awareness of linking these systems rose. The needs of integrating data and interconnecting networks (applications and systems) in business and industry was examined in depth to develop an open communication architecture [5, 29] and further

more frameworks for holistic information systems architectures were defined [33]. Middleware was and is the key player in integrating distributed systems starting 1994 with OMG's object-oriented open CORBA standard: a vendor, platform and program language independent specification [4, 15]. Integration approaches have widened the standardization process and brought new concepts of component ware, integration via web services [3, 7] and enterprise application integration (EAI) solutions for integration on the levels of data, application and processes [31, 23]. All the mentioned integration efforts have led to the new dynamic area of the e-business driven economy which is able to adapt even faster to the business demands [20]. As a matter of fast changes in e-Business life-cycle of virtual enterprises, new ways to preserve this growing amount of business and process knowledge, and transfer of the dynamic content have to be found. The following simulation framework is based on our very recent research project.

### 2. BUSINESS SIMULATION FRAMEWORK

To set-up a business simulation without a framework on the meta-level would end up in a development without extensibility to adapt neither to new demands of the implemented business simulation nor the application of new simulation domains. These major disadvantages of having no continuous life-cycle for simulation systems led us to the development of a simulation framework to ensure a maximum of flexibility for the architecture applied as a corporate simulation and e-learning

instrument. The following top-level requirements were defined for the framework:

- extensible to adapt to new demands
- enable distributed deployment
- simulation domain independence
- ability for import simulation objects, (business) processes and (business) rules from existing e-business or enterprise resource planning (ERP) systems

In asynchronous e-learning systems the reuse of implementation as extensible frameworks [6] is more common as in the area of synchronous e-learning solutions like business simulations. Models and implementations of business simulations are custom tailored to certain needs without developing a general simulation framework as [25] shows for the segment of production management. For our framework to comply with the stated requirements above is divided into the following dimensions of which the components of the simulation framework will be derived:

### **2.1 Simulation Client and Server Environment for Distributed Deployment**

Monolithic architectures, as stand-alone database applications [18], bring along disadvantages which led to client-server architectures in distributed systems. As the simulation framework is deployed in distributed environment client and server components have to communicate via TCP/IP. All used components need to get access and be accessed by standard protocols using a multi-layered architecture. Further there must be the ability for a number of simulation systems to be interconnected.

### **2.2 Access with HTML-Browser and XML-based Client Applications**

As distributed multi-layered simulation framework there has to be access to the server components in all expedient ways. HTML-browser access the simulation components with low featured graphical requirements like administration of the simulation system itself or registration for participants. Is a more featured graphical representation for providing a complex user interface for the simulation clients required, access with client applications and the use of XML communication has to be provided.

### **2.3 Domain and Domain Independent Components**

To enable the framework to be simulation independent applicable there has to be a distinction between domain independent simulation facilities like communication services or operation figures and specific domain dependent components like the used simulation objects.

### **2.4 Production and Administration Environment for Separate Deployment and Assuring Knowledge Preservation in a Repository**

Offering a domain independent open simulation framework, there has to be a central repository to save all modeled knowledge. As models of business simulations can be continuously extended while in use and simulations of different domains can be applied to the framework, the global repository plays an important role. This is an important feature for a corporate group of companies which wish to install the implementation of our simulation framework once and use an instance of the simulation framework for each subsidiary for different domains – preserving a holistic all-in-one mapping. International e-learning communities as university undergraduate schools could develop simulation models for different subjects and share the simulation models using the framework.

### **2.5 Synchronous and Asynchronous Communication Facility; Simulation Inherent and External Communication Facilities**

Communication between the simulation parties and between interconnected simulation systems plays a crucial role in a distributed environment. Therefore synchronous communication facilities are needed for the simulation parties to chat or to send instructions between clients and the server infrastructure. Asynchronous communication is needed for all long-run activities where no immediate feedback is necessary which applies mostly for communication with external resources, e.g. feedback for the user registration process which is realized via SMTP.

### **2.6 Vendor Independence and Import Facilities from E-Business or EAI Solutions**

To ensure a long life-cycle of the simulation framework vendor independence is an important issue. Some vendors use frequently update strategies of their products to keep the turn over high, to change their underlying architecture and APIs to stay in a proprietary way [9]. To adapt to new demands of the fast changing e-business, the simulation framework has to offer import facilities for simulation objects (business objects), (business) processes and rules, and from existing systems. As e-business solutions are set-up of different applications running on legacy systems, ERP systems or enterprise application integration (EAI) solutions, the import of these systems using standardized interfaces reduces the effort of creating new business simulations.

### **2.7 MDA-conform software engineering methods**

As scientific long-term projects [18] and a large number of projects in the information technology have shown, the lack of using iterative and incremental development

processes like specified in the MDA [22] or the Rational Unified Process (RUP) [26] leads to diverse negative side effects in multiple dimensions: (1) Lack of specification, (2) Lack of documentation, (3) Lack of conceptual and technical aspects as extensibility, performance and scalability. The key to develop sustainable, maintainable and extensible systems adequate engineering-methods. We use the RUP to transform requirements into implementation.

## 2.8 High-level Deployment of the Simulation Framework

The dimensions of the stated framework above are summarized as UML deployment diagram in a platform-independent model (PIM):

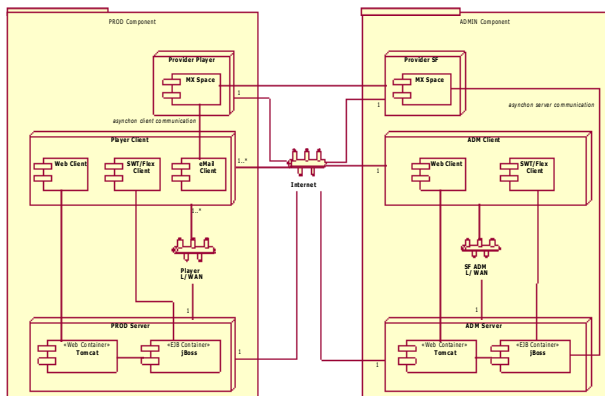

Figure 1: PIM deployment diagram of the simulation framework

## 3. PATTERN DRIVEN MICRO-ARCHITECTURE

System architecture is a complex task layering the architecture in different service subcomponents and in platform specific design issues. A micro-architecture is design pattern-based approach to set-up a holistic architecture to be extensible in the way of features and components, scalability and performance. It structures the patterns to interacting layers of subcomponents addressing services for local or remote objects [2]. Design patterns represent platform and programming language independent solutions for design problems in a certain design context and are a major development in system architecture [8].

The next step towards realizing the stated component-based simulation framework is to structure the system design into subsystems and service units to realize domain and domain independent components. As this is a very dynamic process it forces to use an iterative and incremental software engineering process like the model-driven architecture (MDA) [22, 32].

The server-sided domain independent simulation components in Figure 2 are as follows: *Accounting* (tracking any costs or transactions), *Communication* (between participants and client/server), *SimulationParty* (participants and simulation objects)

and *System* (framework specific system tasks and process engine in the sense of specified workflows).

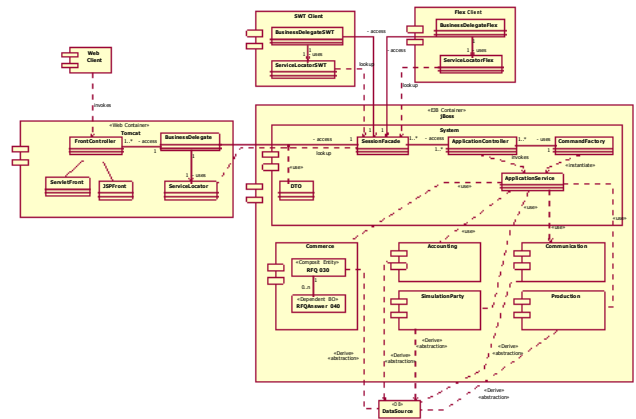

Figure 2: PIM component diagram of the micro-architecture of the core system (partial view)

The client-sided components communicate with the server via Simple Object Access Protocol (SOAP) [28] and offer a communication and simulation client framework. The simulation dependent components are *Production* and *Commerce* and were initialized by the domain of production control [17]. To structure the process of transition from the requirements of framework to the micro-architecture we order the relevant parts in the same sequence as we did in the section before:

### 3.1 Player Client and Server Environment for Distributed Deployment

In a distributed environment the processes of clients and servers have to be separately defined and assigned to the corresponding components. As there are no fat clients intended all major processes for verification of simulation rules are processed server-sided, only basic checking procedures to keep up with unintended mistakes during the simulation period are processed by the client. For this purpose a Session Façade [2, pp341] is used as façade [8, pp185] to decouple and limit client access to the framework and to reduce the network traffic using coarse-grained services. The façade incorporates with the Application Service [2, pp26, pp315] to fulfill use cases spanning business object access as described later on in the domain independent subcomponent.

### 3.2 Access with HTML-Browsers and XML-based Client Applications

To operate the simulation clients as remote clients a Business Delegate [2, pp302; 8, pp144] has to be implemented on the client side. As this component represents a remote object it has to provide a Service Locator [2, pp315] to lookup the server-sided delegate object. Each type of simulation client has to implement its own pair of business delegate and service locator. The communication between clients and server is done

using different standardized protocols. HTML-browsers use HTTP/HTTPS, Java client applications use Java-RMI and SOAP/XML is implemented to extend the client type to Macromedia Flash applications [16] and other remote clients.

### 3.3 Domain Dependent and Domain Independent Components

Domain *dependent* components are business simulation specific objects which are realized as Business Objects [2, pp374] and designed as Composite Entity [2, pp391] as described in the J2EE [12] architecture below. Business objects are highly correlated with the import facilities of external systems and the simulation processes in this framework. As business objects unite business data and logic, they are on the one hand the key for mapping real-world or e-business objects to simulation objects in the way that they are the smallest entity, and no matter how the data is stored in the external system (e.g. split up into different tables), a composite view of the aggregated data is used as Composite Entity. The business logic stored as business processes on external systems and can be imported too. The business objects are aggregated to subsystem components and encapsulated on a higher abstraction layer. The import with direct access to the external systems (e-business, EAI solutions or ERP systems) using J2EE specifications is described later on. Export facilities are not provided in this framework nor the use of Learning Object Metadata [11] for the internal persistence layer as these features are no central issue in our research project.

Domain *independent* components are independent of the business simulation like the system boot-up process, loading, creating, importing and editing of simulations or the administration of the simulation environment. Further the communication objects and the accounting including operating figures to evaluate simulations are domain *independent*. They are on the other hand the key to the dynamics of business simulations: processes belonging to the business object are encapsulated as object's method and processes spanning various business objects are aggregated to use cases and combined as Application Service which represents the domain *independent* simulation engine.

The access to the persistence layer is managed by the J2EE application server [12] and non-DB sources by Data Access Objects [2, pp462]. Data Access Objects abstract and encapsulate the access to the persistence layer in the way that business objects do not have to have information about the persistence store and can transparently access all kinds of data like XML feeds or flat files.

### 3.4 Production and Administration Environment for Separate Deployment and Assuring Knowledge Preservation in a Repository

The framework is designed to be used as

multi-deployment implementation with a distinction between the production systems and the administration system containing the global repository (Figure 1). As there is the need of a central repository to back-up the simulation objects, the business processes and to preserve the modeled dependencies of all production systems, it is further used for documentation purposes. The set-up of new simulation models and the transfer to other simulation instances of this simulation framework is managed by the administration environment.

### 3.5 Synchronous and Asynchronous Communication Facility; Simulation Inherent and External Communication Facilities

To enable simulation inherent client to client, client to server communication, and external communication facilities, the communication component is part of the domain *independent* simulation components. As there is a multi-view to the components of the business simulation framework and the micro-architecture, these views overlap. Synchronous and asynchronous system communication is realized with the standard platform API. To summarize at this point for the J2EE architecture: Java-RMI is used for object calls, SOAP/XML for client-server and server-server communication and SMTP for e-mail.

### 3.6 Vendor Independence and Import Facilities from E-Business or EAI Solutions

Vendor independent development is realized by using a J2EE architecture as it is vendor, operating system and hardware independent. Depending on the application demands the simulation framework can be deployed on small, medium or large scale systems, standalone or clustered. The distributed J2EE architecture offers a connector architecture (JCA) [13] to enable all major platforms and vendors to provide their own resource adapters or implement the needed JCA connector with minimal interface programming themselves. Further as stated in the requirements for the framework, the only way to deliver an extensible system to adapt to new demands is to lengthen the life-cycle of the application by using sustainable and open standards. Our simulation framework therefore offers import facilities using JCA or indirect import of any desired semantics using XML or CSV format.

## 4. DISTRIBUTED J2EE ARCHITECTURE AND ITS IMPLEMENTATION

The sections above described the requirements, the deployment and the micro-architecture (both PIMs) of the framework. Following the MDA the next step towards the implementation is the transfer of the PIM to a Platform Specific Model (PSM) [22] to ensure the system architecture keeps the requirements: extensible, distributed deployment, simulation domain independent

and import capabilities. The chosen J2EE [12] platform and its implementation specific topics follow.

#### 4.1 Basic Rules for Transformation of the PIM to PSM J2EE Architecture

To ensure an adequate and coherent transformation from the PIM to the PSM some basic rules were set up:

1. Application of all the capabilities of the J2EE server: no server-sided plain old java objects (POJOs), no bean-managed persistence (BMP)
2. Favour declarative over programmatic solutions: use the mightiness of the deployment descriptors
3. Use sustainable and open standards for all interfaces: SOAP/XML for client-server and server-server communication

#### 4.2 Design of the Persistent Domain Model

Following the basic transformation rules the data access to the persistence layer is implemented using container-managed persistence (CMP) thus the container requests, fetches and manages the life-cycle of the entity beans. This reveals performance advantages, bean pooling optimization, and no mix up of framework code and code for the persistence layer.

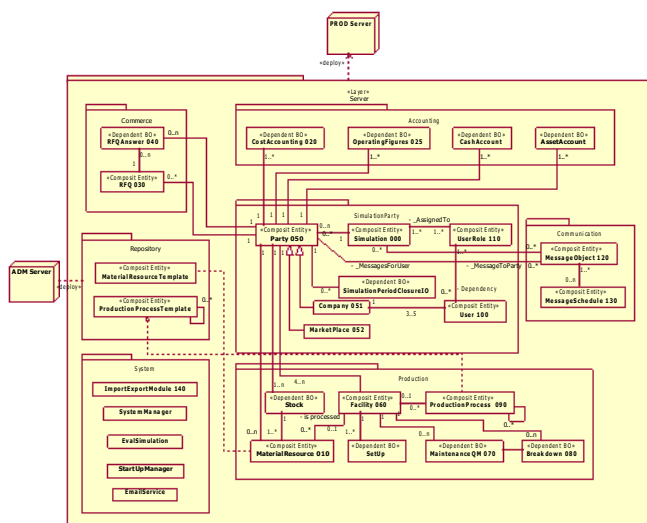

Figure 3: PSM of persistent objects as J2EE design model for implementation (partial view)

The relationship between persistent objects are defined declarative in the deployment descriptor and are managed by the J2EE container: referential integrity, cardinality, cascading delete, and using EJB Query Language (EJB QL) for portable query code [12]. To ensure performance, extensible and scalability, the components and its business (domain) objects are implemented as Composite Entity [2, pp 391] which enables the object-oriented aspect of capsulation of business objects further more. For non-database

persistence like XML feeds, legacy systems, LDAP repositories or flat-files, Data Access Objects [2, pp 460] are implemented.

#### 4.3 Import Facilities using JCA and JMS

Using the J2EE technology platform enables synchronous and asynchronous access via JCA and Java Message Service (JMS) [14] for the import of data and process information of existing e-business or ERP systems. The JMS API enables direct access to external JMS-compliant systems and the implementation of the JMS import facilities manifest as minor expenditure. JCA resource adapters are available for all major systems as middleware infrastructure like IBM MQSeries [10] or ERP systems like SAP's new Netweaver Architecture [30] and can be plugged-in for data import as needed.

## 6. CONCLUSION

The presented component-based framework for distributed business simulations in e-business environment offers a new conceptual way as an extensible micro-architecture to implement this framework once and extending it to future requirements of diverse domains for simulation and e-business solutions. The pattern driven micro-architecture ensures further development of the framework without pitfalls of scalability or performance problems. We believe new e-learning solutions for preserving and transferring the inherent dynamic system knowledge of rapid changes in e-business will adopt similar strategies as the frameworks introduced in this paper. Future research in combining our simulation framework with Learning Object Metadata for export to other simulation and e-learning systems or for direct access for the persistence layer would widen the framework for even more interoperability.

### ABSTRACT

Despite the recent downturn in Internet and telecommunication sectors, e-commerce is forecasted to continue to grow and corporate websites have remained as important communication channels for both businesses and consumers. However, many multi-nation corporations (MNCs) use the same business websites for their business transactions in all of their business locations, even across national boundaries. Does this kind of "one website fits all" mentality of using Web technology really work well in reality? Does national culture matter in terms of influencing the adopting of Web technology for commercial usage in MNCs? Whether corporations in different countries/cultures use Web technology differently in their commercial websites? This paper intends to explore the above important research issues through examining and comparing the usage of commercial websites among corporations in two different countries: Singapore and the United States.

**Keywords:** Web, Electronic Commerce (Business), USA, Singapore, Global

### 1. INTRODUCTION

Over the last few years the Internet has evolved to a platform that is enabling a new generation of businesses. Companies have realized the tremendous opportunities the Internet offers and have established an online presence with sound business models. In general, e-commerce can be defined as buying, selling of products, services, and/or information that use the Internet and Web technology (Hof & Hamm, 2002). E-commerce is proved to have abilities to enhance economic growth, reduce barriers of market entry, improve efficiency and effectiveness, keep inventories lean, and cut cost (Madden & Coble-Neal, 2002).

At the same time, consumers have found the power on the Internet: convenience, greater choice, vast amount of information, and time savings, are not going to let challenging economy stop them to taking advantage of it. The number of business to consumer (B2C) spending is expected to reach \$95 billion in 2003, and could reach \$250 billion in 2005. Moreover, the business of business (B2B) online transactions now stand at \$2.6 trillion, not the originally expected \$1.3 trillion, and analysts are revising their estimates of productivity gains sharply upward (Mullaney, Green, Arndt, Hof, 2003). Indeed, e-commerce has transformed entire industries globally and the Net is really "changed everything" and even more startling changes are on the horizon.

### 2. RESEARCH BACKGROUND

This paper intends to study and compare the Internet's business usage among corporations in the U.S. and Singapore, in order to explore whether national culture could be an important factor influencing the Internet usage in business corporations. These two countries are from two different continents across the globe and can be viewed to best represent members of its respective continent.

The U.S. has the largest number of online users in the world. The U.S. broadband subscriptions which allow speedy connection to the Internet doubled since 2001 and are growing at 56% annually. It is expected to reach 40 million households at the end of 2003 (Forrest Research, 2003). Studies have found that Internet and Web are not only used to generate revenues, but also used as tools to increase productivity in the U.S. In fact, productivity growth is doubled as the Web proliferated since 2000 (Mullaney, Green, Arndt, and Hof, 2003). More and more companies are utilizing the Internet medium for advertising purpose to attract customers online. According to AdRelevance report in 2003, a division of market researcher Nielsen-NetRatings, big advertisers are showing renewed interest in online advertising after the downturn of the economy. Purchases of Web ads rose to \$3.2 billion in the first half of the 2003, jumped from \$2.8 billion in the same period of 2002. "Search-related" advertisements, which appear alongside results on well-trafficked Web-search sites, are particularly popular (Mangalindan, 2003). This is not only helping boost the sales and fortunes for the businesses, it also helps businesses to target their potential customers.

Singapore, on the other hand, is the seventh in terms of preparedness for e-commerce. Singapore government has also been extremely supportive of its e-commerce activities. It has played a multi-faceted role of being both the user and promoter of e-business application in the country. Concrete steps have been taken to position Singapore as a global node and regional hub in e-commerce. The Electronic Commerce Master plan was launched in 1998 and the legal framework has been updated through the passing of the Electronic Transaction Act. The government strives to build up research capability by encouraging leading e-commerce research companies to be based in Singapore. Singapore encourages local establishments to link up with international research centers in order to learn from

others and to share their expertise. The number of Internet dial-up subscribers in Singapore increased from 139,000 in January 1997 to over 1,943,800 in 2001, placing Singapore at the seventh out of 60 countries in terms of preparedness for e-commerce. Statistics have shown positive outbreak of revenues from e-commerce. For instance, according to the Info-communications Authority of Singapore (IDA), the revenues from e-commerce sector was to top about US\$1.4 billion in 2001 as compared to US\$659 million in 2000. Statistics have also shown a higher amount of people buying items such as airline tickets, books and CDs, and reserving hotel rooms through the Web.

### 3. RESEARCH QUESTIONS

Although commercial websites are expected to grow to 200 millions by 2005 (Palmer, 2002), the business usage of Web technology to reach a large number of customers worldwide remains a big challenge for many multi-nation corporations (MNCs). Customized Web design with multi-language support alone, however, is not enough. Website builders must also consider political, cultural, social, and legal differences in the global environment. For example, culture provides people with a sense of identity and an understanding of acceptable behavior within society. Culture includes values, shared beliefs, or group norms that have been internalized by individuals with some modification (Hofstede, 1980). In addition, culture influences peoples' perceptions and their interpretation of the world. It influences their expectations, values, beliefs, attitudes, and ultimately their behaviors in everyday life (Adler, 1991). Groups of people have unique backgrounds because of their shared history, economy, geography, religion, and demographics. Therefore, it is important for MNCs to understand how culture may influence the business usage of Web technology on a global scale.

The U.S. is traditionally recognized as having a strong culture based on individualism that stresses independence of each individual within a society. On the other hand, Singapore focuses more on collectivism and emphasizes the goals of the group over personal goals, stresses conformity and in-group harmony, and defines the self in relation to the group (Lu, Rose, & Blodgett, 1999; Triandis, 1995).

Although several studies addressed the usability and design of Web sites (e.g., Palmer 2002, Paerrow 2000, Nielsen 2000, Shneidermann 1998), none have extended their studies to across national boundaries to examine the website usages in a global environment to our best knowledge. Therefore, a study in this topic will help fill the gaps. This study intends to examine and compare the Web usage of businesses among corporations in the U.S. and Singapore. The two countries are from two different continents across the globe and can be viewed to best represent members of its respective continent with its

culture background. The specific research questions are:

- *What are the main features of the corporations' web sites in these two countries?*
- *What are the important contents that are normally included in most commercial web sites in these two countries?*
- *Is the usage of web sites in business corporations related to the characteristics of the industries that the corporations belong to?*
- *Are there any differences of using web sites in these two countries?*
- *Does culture play a role in the site differences in these two countries?*

### 4. RESEARCH METHODOLOGY

In order to do a comparative analysis of commercial website usage among corporations in the two countries, a common assessment framework was used to collect data and conduct the comparative analysis. The framework consists of 14 main categories describing the commercial usage of web technology (e.g., Cheung and Huang, 2002; Liu, Arnett, Capella, and Beatty, 1997), as shown below.

- Company overview/information: Brief history; how the company organized and operates; company capability; general business environment; challenges, etc.
- Products/services: Main products and services.
- What's new: News releases for the products and services; updated news; pertinent industry information; new announcements; hot topics, etc.
- Search: Search engine for users to locate available interested items within the company's home page.
- Employment/Career opportunities: Available opportunities for certain positions and their descriptions.
- Interactive feedback: Requesting viewers to respond about their feelings/suggestions about a company and/or web home page.
- Customer service/assistance: Answering questions; sending forms to relevant person for products/services support; providing necessary help, etc.
- Index/directory: Company's Web site direction or map; location distribution; department addresses; office phone numbers, etc.
- Financial/Investment facts: Detailed financial performance
- Links to other sites: Connection with Internet yellow page, weather, stock, quotes, news groups or third party vendors.
- Online business: For information transformation on ordering/banking through the company's home page.
- Guest book: Requesting customers to sign in by providing their names and addresses.
- FAQ: Questions and answers for the frequently asked questions about the company, its products, its services, its website, or something else.

- Messages from CEO: Greetings and brief introductions from CEOs

Then the authors of this paper accessed to more than 700 commercial web sites and collected data based upon the framework. More specifically, Fortune 500 corporations were chosen as the data points representing US corporations. These companies' Web sites generally provide a leadership of using information technologies (Liu et al, 1997). In Singapore, a total of 250 Web sites were randomly selected based on queries results of using search engines Yahoo and AltaVista. These corporations' web sites represented 11 main industries in Singapore (Cheung and Huang, 2002). In addition, an extensive search has also been done to collect the most updated information on e-commerce in these two countries, using mainly the search engine of GOOGLE and OCLC library search.

## 5. RESEARCH FINDINGS

### 5.1 Company Size with regards to E-commerce embracement

#### U.S.

Results from the United States regarding e-commerce embracement seem to differ from those of Singapore. Many small sized companies are moving faster and getting dramatic results using direct selling on the Web. They tend to take more advantage of the low cost advertising and saved space on the Web to generate revenues, whereas most of the large companies such as the Fortune 500 tend to mainly announce their presence and promote their companies' image, enhance public relations, etc.

#### Singapore

On the other hand, the growth of e-commerce has been unevenly distributed. Large enterprises have generally been more ready to embrace e-commerce than small enterprises. 96% of the large enterprises are equipped with Internet access as compared to 86% for the small enterprises. Also, about 61% of the large firms have their own websites, compared to only 32% among the small enterprises.

### 5.2 Industry's Web Presence

#### U.S.

As indicated above that the Fortune 500 companies were selected to represent the United States because they usually provide the leadership in the use of information technology. Industry types are classified into 11 divisions by Standard Industry Code (SIC) of which, the Fortune 500 comprises of 9, with statistics of percentage Web presence shown below in Table 1.

In the case of the Fortune 500, the Transportation industry seems to be the leader in Web presence. However, it should be noted that the industry category is

classified differently from how it is for Singapore. For Singapore, the Retail and Wholesale industries are combined into one; whereas for the Fortune 500, the Retail Trade and Wholesale trade are distinguished, thus making the statistics percentage lower than that of Transportation industry. Nevertheless, it is evident that the Retail/Wholesale industry will place the highest on the scale.

Table 1: Industry's Web Presence in U.S.

Industry	WWW presence
Transportation, communication, electric, gas, sanitary services	87.10%
Retail Trade	68.10%
Manufacturing	63.60%
Finance, insurance, real estate	53.30%
Services	51.40%
Agriculture, forestry and fishing	47.40%
Wholesale trade	42.30%
Construction	14.30%
Mining	0.00%

Another internet-related activity big company involved in is e-procurement. Even though the connection on the Internet has been established, most companies do not seem to take full advantage of it for e-procurement. According to a study by Hurwitz Group, less than one-third of Fortune 500 businesses order strategic goods from online suppliers. VP of e-business Strategies at Hurwitz Group said despite the promise of tremendous benefits from e-Procurement, including perceived savings of up to 50 percent in purchasing costs, most companies are not measuring these anticipated benefits.

Most e-procurement systems being utilized lack support for complex procurement processes, including contract management and negotiation. The study from Hurwitz Group stated that companies may work with thousands of suppliers, but fewer than 100 suppliers were linked to their e-procurement system. The study also found most companies that do make purchases online are performing indirect purchases of maintenance, repair, and operational goods and services instead of using e-procurement to purchase direct goods to automate production or manufacturing processes.

#### Singapore

The SES – Security Exchange of Singapore classified all listed businesses in Singapore into 5 big categories: industrials, finance, hotels, properties, and plantation (Cheung and Huang, 2002). Based on this categorization, another set of categories of businesses has been further developed, dividing the Singapore businesses into 11 categories, including:

1. Retail/Wholesale Trade
2. Information Technology/Computer
3. Manufacturing

4. Public Utilities
5. Tourism
6. Transportation
7. Finance/Banking
8. Design/Advertising/Press/Media
9. Properties and Holding (Real Estate)
10. Human Resource/Consultation
11. Other

Retail/Wholesale industry takes the lead in WWW business presence with 27.6%. This is an interesting finding for Singapore since the industry type that takes the lead in Web presence is not Information Technology, which places 2<sup>nd</sup> on the scale with 22.8% Web presence. This difference is explained by the fierce competition in retail/wholesale industry. Singapore is a small country with the population of about 4 million (The World Fact Book 2002), with many big international retail corporations competing against each other. With such tight competition, small and medium sized companies have turned to e-business as their solution since the Internet provides inexpensive and mass marketing channels, versus the unbearable cost of advertising on TV as well as other mass media. Another important factor to note is the Singapore government has been very supportive of the development of its IT industry. The IT industry has received substantial government funding as well as preferential treatment under government tax and financial regulations and policies (Cheung and Huang, 2002). However, the difference in the total number of companies going online has indicated that the adoption of WWW technology is most likely not driven by government backup, but rather by competitive marketing forces. These two industries are classified as early adopters in the WWW presence. The next categories of industry are classified as early majority in terms of adopting WWW for commercial use. Statistics on each industry's Web presence is summarized below in Table 2.

Table 2: Industry's Web Presence in Singapore

Industry	WWW presence
Retail/Wholesale	27.6%
IT	22.8%
Design	8.80%
Manufacturing & tourism	6.80%
Real Estate	6.40%
Consultation service	5.60%
Transportation	5.20%
Financial/Banking	2.8%
Public Utilities	0.8%

The low percentage of Web presence of Finance/Banking industry at the time of the research is explained by the fact that the industry deals with money and volatile information. Its transactions require a high level of security guarantee. Since the Internet is not truly known for being the safest place to store such

information, i.e. there are still problems with the system being hacked into. Thus, this could explain somewhat the reason for the low figure in Web presence of banking industry. A general chart showing the percentages of companies that have web pages in different industries across the two countries is also composed as following in Figure 1.

Figure 1 shows that the U.S. tends to lead WWW presence in Manufacturing and tourism industry, whereas Singapore leads the WWW presence in its Retail/Wholesale sector. More specifically, the top three industries with WWW presence in US are Transportation/Communication/Electronic, Retail Trade and Manufacturing; the top three in Singapore are Retail/Whole Sale, Information Technology, and Design. Therefore, the two countries differed in web presences of industries.

### 5.3 Features on Commercial Web Sites

#### U.S.

The main features found on websites of Fortune 500 include: products and services, company overview, feedback, what's new, financial facts, customer service, search, employment opportunities, guest book, Index or directory, online business, links to other sites, CEO messages and frequently asked questions (FAQ). It indicates that most companies go online to introduce their products/services to a larger market target at a lower cost.

#### Singapore

Based on the study conducted by Huang (2002), 100% of Singapore web sites contain their companies' names, images, and information of their products/services. The next most popular feature is online information exchange (26.8%) and the third in line is customer support (19.6%). For Singapore Web sites, the least likely purpose of the homepages is to achieve sales on the Internet (17.2%). The result indicates that trading activities on line had not fully bloomed in Singapore. Companies set up homepages mainly to publicize the companies and their images, rather than to take advantage of the profit-enhancing activities available on the Web. The Internet security issues and customer's preference of old purchasing behaviors could be the reasons contributing to the lack of interest from most corporations in Internet sales.

Web in Singapore aims more at customer support and information exchange, whereas Internet sales are most emphasized by the Retail industry. There are a number of barriers that create difficulty for the consumer online retail business. One of the barriers is the fact that Asia does not have the same big base of installed personal computers. On average, there are 0.01 personal computers per person versus 0.40 in the U.S., according to IDC. Another barrier is the built-in habit of the users. There are shopping malls everywhere in Singapore and

Figure 1: WWW Presence in Singapore and the U.S.

Figure 2: Web Features in Singapore and the U.S.

consumers generally like to feel and touch the products, try and test them out and compare the prices prior to purchasing them. Furthermore, a big concern is the use

of credit card online. Even though more people are spending time online, when it comes to purchasing, they are still reluctant due to concerns over the security of

credit card purchases and personal information. The problem with using credit card online has been addressed by a verification service however, called "Verified by Visa", where customers use personalized password to serve as an additional verification point. When they buy something from a website that is "Verified by Visa", they are given access by entering their password as at ATM machines.

Figure 2 provides a comparison of the frequency of features found on Web sites of the two different countries. On average, the top 3 features utilized on any Web site are products/services, company overview, and feedback, which reinforces the main purpose for corporations going online at this point, which is to reach a large market to promote acknowledgement of their products/services, and to pronounce the existence of the company. Feedback also allows the companies to get customers' ideas and opinions on how they are doing and what could be improved for them to better serve their customers. Other features are not uniform across the two countries. In other words, they are on websites of one country but not found as common on websites of another country. Customer service is also present on all websites but appears to be the lowest in Singapore, which indicates the fact that Singapore companies need to redesign their web site in such a manner that can provide customer services to the extent possible.

## 6. DISCUSSIONS AND IMPLICATIONS

Our cross-country comparison study indicated that on the usage of commercial web sites of corporations in the two different countries is different from each other, in terms of the three specific aspects, web presence in different industries, web features used in their web sites, and the relationship between corporation size and commercial web sites, etc. Corporations have spent millions of dollars in developing web sites for commercial purposes in the past years. Different ways of using commercial web sites would reflect different needs and characteristics of local businesses in the two countries. As a result, the one-size-fits-all method of designing and using commercial web sites may not work well when crossing national geographical boundaries and/or cultures. Therefore, when designing and developing commercial web sites and/or e-commerce systems for corporations in different countries, national culture could be an important factor to be considered in order to design a successful and effective commercial web site for corporations in another culture/country.

The majority of companies in Singapore and the Fortune 500 companies are using the Internet medium mainly for advertising purpose, to announce their existence rather than to generate revenue. However, they have all realized the huge potential provided by their Web

presence and have implemented strategies to attract more hits to their sites, as well as to generate more revenues from their Web presence. As far as the features on the Web sites, even though the companies are physically dispersed, their Web presences share fairly similar standards for content display. The features most frequently found on all websites across the two countries are Products/Services, Company Overview, Feedback and Customer Service. The percentage of their use may differ, i.e. Singapore has a low percentage on Customer Service compared to the Fortune 500; however, in general, they all mean to expose the companies to the public to promote knowledge of the public toward their products/services provided, as well as to enhance public relations, to reach global customers, and to get feedback from customers to improve the way they can do business and better serve the customers. Regardless of the fact that industries are classified somewhat differently across the two countries; however, the Retail industry seems to be the one with the highest Web presence in all, also the one that generates the most revenue from its web presence compared to other industries. Despite any drawback in the economy or concern over security on making purchases online, it is predicted that revenues generated by businesses conducted via the Web will be on the rise across the two countries, defining the new age of technology.

# A Personalized Recommender System Based on Explanation Facilities Using Collaborative Filtering

Do Hyun Ahn, Hee ae Lee

School of Business Administration, Kyunghee University Seoul, 130-701, Korea  
adh@khu.ac.kr, leeheeae@hanmail.net

## ABSTRACT

Collaborative filtering (CF) is the most successful recommendation method, but its widespread use has exposed some limitations, such as sparsity, scalability, and black box. Many researchers have focused on sparsity and scalability problem but a little has tried to solve the black box problem. Most CF recommender systems are black boxes, providing no transparency into the working of the recommendation. This research suggests an improved CF recommender system with explanation facilities to overcome the black box problem. Explanation facilities make it possible to expose the reasoning and data behind a recommendation. Therefore, explanations provide us with a mechanism for handling errors that come with a recommendation. Furthermore, it is proposed to use web usage mining and product taxonomy to enhance the recommendation quality for e-commerce environment. For such purposes, it is developed a recommender system named WebCF-Exp, Web usage mining driven Collaborative Filtering with Explanation facilities. To test the performance of WebCF-Exp, EBIB research internet shopping mall and explanation interfaces are developed. Experiments are conducted with the data provided by EBIB Research Internet shopping mall.

**Keywords:** Collaborative Filtering, Recommendation system, Explanation, Internet shopping mall

## 1. INTRODUCTION

The continuous growth of the Internet and e-commerce has allowed companies to provide customers with more choices on products. Increasing choice has also caused product overload where the customer is no longer able to effectively choose the products he/she is exposed to. A promising technology to overcome the product overload problem is recommender systems that help customers find the products they would like to purchase. To date, a variety of recommendation techniques have been developed. Collaborative Filtering (CF) is the most successful recommendation technique, which has been used in a number of different applications such as recommending movies, articles, products, Web pages, etc. [1,2,3,7,10,11]. However, its widespread use has exposed some limitations, such as sparsity, scalability, and black box. Many researchers have focused on sparsity and scalability problem but a little has tried to solve the black box problem. According to Herlocker et al.[6], most CF recommender systems are black boxes, providing no transparency into the working of the recommendation.

This research suggests an improved CF recommender system with explanation facilities to overcome the black box problem. Explanation facilities make it possible to expose the reasoning and data behind a recommendation. Therefore, explanations provide us with a mechanism for handling errors that come with a recommendation. Furthermore, it is proposed to use web usage mining and product taxonomy to enhance the recommendation quality for e-commerce environment. Web usage mining populates the rating database by tracking customers' shopping behaviors in the Web, thereby leading to better

quality recommendations. The product taxonomy is used to improve the performance of searching for

nearest neighbors through dimensionality reduction of the rating database. For such purposes, it is developed a recommender system named WebCF-Exp(Web usage mining driven Collaborative Filtering with Explanation facilities). To test the performance of WebCF-Exp, EBIB (e-Business & Intelligence Business) research internet shopping mall and explanation interfaces are developed. Experiments are conducted with the data provided by EBIB Research Internet shopping mall.

The remainder of this paper is organized as follows. Section 2 reviews the past researches related to recommender systems and explanation. Section 3 and section 4 provide our research framework and system architecture. Section 5 describes experimental evaluation and section 6 finally provides some conclusions and future works.

## 2. LITERATURE REVIEW

### 2.1 CF-based Recommender Systems

CF-based recommender systems recommend products to a target customer according to the following steps [11]: (1) A customer provides the system with preference ratings of products that may be used to build a *customer profile* of his or her likes and dislikes. (2) Then, these systems apply statistical techniques or machine learning techniques to find a set of customers, known as *neighbors*, which in the past have exhibited similar behavior (i.e. they either rated similarly or purchased similar set of products). Usually, a neighborhood is formed by the degree of similarity

between the customers. (3) Once a neighborhood of similar customers is formed, these systems predict whether the target customer will like a particular product by calculating a weighted composite of the neighbor's ratings of that product (*prediction problem*), or generate a set of products that the target customer is most likely to purchase by analyzing the products the neighbors purchased (*top-N recommendation problem*). These systems, also known as *the nearest neighbor CF-based recommender systems* [2,10,11] have been widely used in practice. However, its widespread use has exposed some limitations, such as sparsity, scalability, and black box.

## 2.2 Web Usage Mining

Web usage mining is the process of applying data mining techniques to the discovery of behavior patterns based on Web log data for various applications. The overall process of Web usage mining is generally divided into two main tasks: data preprocessing and pattern discovery. Mining behavior patterns from Web log data needs the data preprocessing tasks that include data cleansing, user identification, session identification, and path completion. Mobasher et al.[9] presented a detailed description of data preprocessing methods for mining Web browsing patterns. The pattern discovery tasks involve the discovery of association rules, sequential patterns, usage clusters, page clusters, user classifications or any other pattern discovery method. Lee et al.[8] provided a detailed case study of clickstream analysis from an online retail store. To measure the effectiveness of efforts in merchandising, they analyzed the shopping behavior of customers according to the following four shopping steps: product impression, click-through, basket placement, and purchase. It has been recognized that Web usage mining gave better recommendation quality in the CF recommendation procedures [1,3].

## 2.3 Product Taxonomy

Product taxonomy is practically represented as a tree that classifies a set of products at a low level into a more general product at a higher level. The leaves of the tree denote the product instances, SKUs (Stock Keeping Units) in retail jargon, and non-leaf nodes denote product classes obtained by combining several nodes at a lower level into one parent node. The root node labeled by All denotes the most general product class. For example, Figure 1 shows product taxonomy for an internet shopping mall, where "SKU00", "SKU09" and "SKU10" are classified into "Outwears", and etc. A number called level can be assigned to each node in the product taxonomy. The level of the root node is zero, and the level of any other node is one plus the level of its parent. Note that a product class at a higher level has a smaller level number. The product taxonomy of Figure 1 has four levels, referred to as level 0 (for root), 1, 2, and 3. Recently, the usage of product taxonomy in data

mining has been emphasized by many researchers [3,5,7] since it reflects domain specific knowledge and may affect the results of the analysis.

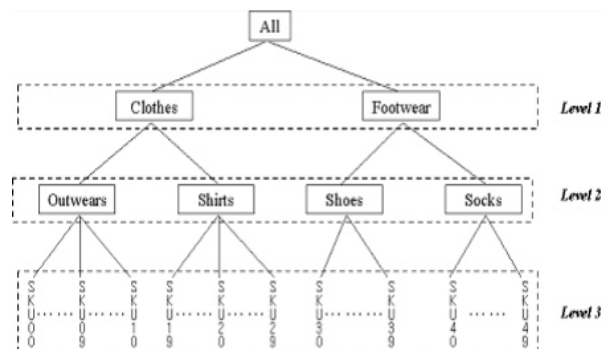

Figure 1. Example of product taxonomy

## 2.4 Explanation

Most CF recommender systems are black boxes, providing no transparency into the working of the recommendation. Therefore, a user is given no indicators to consult to determine when to trust a recommendation and when to doubt one. The problem has prevented acceptance of CF-based recommender systems in all but the low-risk content domains. Explanation facilities make it possible to expose the reasoning and data behind a recommendation. Therefore, explanations provide us with a mechanism for handling errors that come with a recommendation. Building an explanation facility into a recommender system can benefit the user in many ways. It removes the black box from around the recommender system, and provides transparency [4,6]. According to Herlocker et al.[6], some of the benefits provided by the explanation facilities are:

**Justification:** User understanding of the reasoning behind a recommendation, so that he/she may decide how much confidence to place in that recommendation.

**User Involvement:** User involvement in the recommendation process, allowing the user to add his knowledge and inference skills to the complete decision process.

**Education:** Education of the user as to the processes used in generating a recommendation, so that he/she may better understand the strengths and limitations of the recommendation capability of the system.

**Acceptance:** Greater acceptance of the recommender system as a decision aide, since its limits and strengths are fully visible and its suggestions are justified.

## 3. METHODOLOGY

WebCF-Exp is a CF-based recommender methodology based on Web usage mining, product taxonomy, and explanation facilities to improve the recommendation quality and system performance of current CF-based recommender systems. The overall procedure of WebCF-Exp consists of two main methods as shown in Figure 2: recommendation method and explanation

method. The input data consist of Web server log files, product database and purchase database. The endmost output is the personalized product recommendation list with explanation facilities.

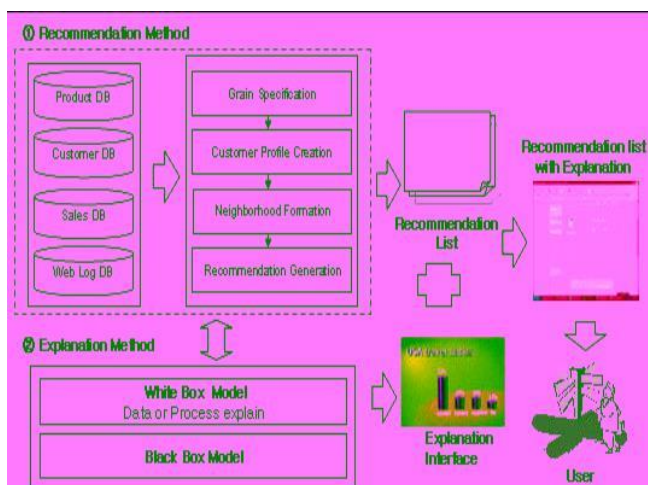

Figure 2. Overall procedure of WebCF-Exp

The recommendation method is divided into four phases: grain specification, customer profile creation, neighborhood formation, and recommendation generation. In the grain specification phase, all products in the database are hierarchically grouped based on the level of aggregation (called *grain*) specified from the marketing manager. Such a product grouping enables the following phases to handle products in the reduced dimensional space. Target customer's preference across products are analyzed and used to make customer profile in the customer profile creation phase. Tracking individual customer's previous shopping behavior in an e-commerce site is used to make preference analysis. The neighborhood formation phase is to form a similarity-based neighborhood between a target customer and a number of like-minded customers. Finally, the recommendation generation phase produces the top-N recommendations based on the shopping behavior of neighbors.

The explanation method consists of white box model and black box model. In white box model, we focus on techniques to justify that the recommendation is indeed performing each of the above phases to the satisfaction of the user and his/her current context. Let us examine each of the steps in more detail, focusing on two components that we need to explain: the process and the data. Often, there is not the opportunity or possibly the desire to convey the white box model. In such cases, the black box model is used to produce recommendations. In black box model, we focus on ways to justify recommendation that are independent of the mechanics.

#### 4. WebCF-EXP RECOMMENDER SYSTEM

For the implementation of the proposed recommender methodology, a recommender system is developed using

agent and data warehousing technologies. WebCF-Exp recommender system consists of four agents as shown in Figure 3: Web log analysis agent, Data transformation agent, Recommendation agent, and Explanation agent. Web log analysis agent manages Web log database through periodic collecting, parsing and analyzing Web server log files such as access logs, referrer logs, agent logs and cookie files. Thus, the users can easily access and analyze it like other operation databases. Data transformation agent creates and manages the data mart that provides data indispensable to accomplish recommendation tasks. Recommendation agent makes a personalized recommendation list for each target customer. Explanation agent provides interfaces which expose the reasoning and data behind a recommendation.

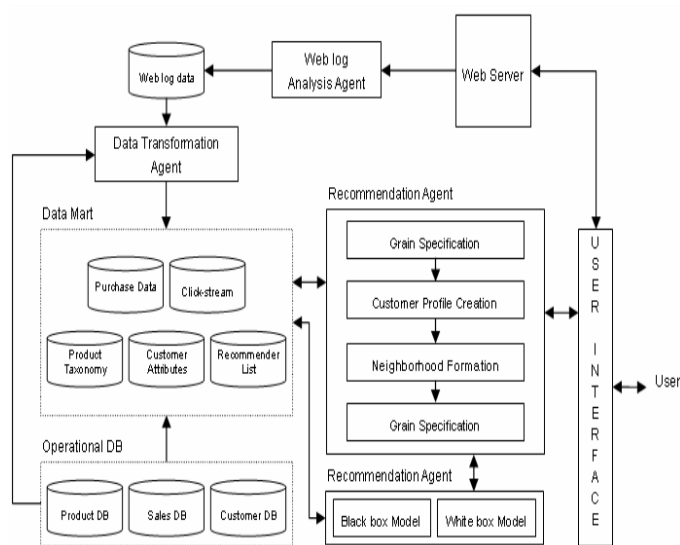

Figure 3. The architecture of WebCF-Exp recommender system

We developed twenty different explanation interfaces to test the recommendation quality. Figure 4 shows one of twenty explanation interfaces.

Figure 4. An example of explanation interface

#### 5. EXPERIMENTAL EVALUATION

In order to evaluate the our suggested recommender

system, we built the prototype of WebCF-Exp recommender system, EBIB Research online shopping mall and explanation interface. We also performed a survey to find the most suitable explanation interface for our recommender system and evaluate the effectiveness of explanation.

### 5.1 Experimental Design

We conducted the experiment from October 2, 2003 to November 26, 2003, and analyzed the user data between November 18 and November 26, then evaluated the performances of the recommender system. We also surveyed the customers who received our recommendation and say the explanation interface at the same time. In order to make WebCF-Exp recommender system more understandable, we would explain the process of purchase and recommendation. Programs to perform all our experiments were implemented using Visual Basic 6.0. MS-Access was used to store and process all data necessary for our experiments. EBIB Research online shopping mall was made by MS-SQL Server 2000, WindowsNT2000 Web Server IIS5.0, and ASP(Active Server Page).

Study participants were presented with the following hypothetical situation:

You enter the site of EBIB Research online shopping mall and sign up. You have to submit such data as ID, name, e-mail, birthday, gender and address. When you finish, you will receive 1,000 dollars and can purchase what he want to have. After you log in the site, the server will collect all log data about you. Through the web log agent, the WebCF-Exp recommender system preprocesses web log files and maps click, basket and purchase with "goods\_view.asp", "cart\_list.asp" and "cart\_pay.asp" to extract data related customers' shopping behavior.

Each user was then provided with a different explanation interface, and asked to rate on a scale of 1-5 how likely they would purchase the recommended goods. A successful explanation interface can make a customer more preferable to purchase the recommended goods, and feel the explanation useful and exciting. Therefore we should make it communicate and understand easily and help with the customer's decision making if building an explanation facility into a recommender system. In our research we performed a survey to find the most suitable explanation interface for our recommender system and evaluate the effectiveness of explanation. There are two key research questions that we are interested in answering about the use of explanations with WebCF-Exp recommender system.

The first question is about the understandability and suitability.

Q1: Are the explanation interface understandable and effective?

The goods was explained by the explanation interfaces that we randomly choose from the 20 interfaces, and the question was rated on a 5-point Likert scale ranging from "very difficult" to "very easy."

The second question is about the usefulness of the explanation interface.

Q2: Can the explanation interface increase the acceptance of recommended goods?

The question was rated on a 5-point Likert scale ranging from "not at all" to "very much."

### 5.2 Experimental Results

(1)Quality comparison of WebCF-Exp and benchmark CF

To compare the quality comparison of WebCF-Exp with that of the benchmark CF algorithm, we performed an experiment to measure *precision* and *recall*. *Precision* and *recall* have been widely used in recommender system research [2,3,11]. Table 1 shows the *precision* and *recall* provided by two algorithms. Looking into the results shown in Table 1, we can see that WebCF-Exp is about 159% and 116% better than benchmark CF, respectively.

Table 1. Quality comparison of WebCF-Exp and benchmark CF algorithm

	WebCF-Exp	Benchmark CF
<i>Precision</i>	0.196	0.123
<i>Recall</i>	0.495	0.425

(2)The result of survey on explanation facilities

The first question is about the understandability and suitability. Table 2 shows mean response and standard deviation of users to explanation interfaces. Looking into the results shown in Table 2, explanation with simple graph and description is better than other explanation types.

The second question is about the usefulness of the explanation interface: Can the explanation interface increase the acceptance of recommended goods? Looking into the results shown in Table 3, the higher customer understands explanation interface, the more helpful customer purchase a product.

Table 2. The result of Q1

	Explanation Interfaces	Mean Response	Std Dev
1	Neighbor ratings (5 stars)	3.806	0.992

## 6. CONCLUSION

Collaborative filtering (CF) is the most successful recommendation method, but its widespread use has exposed some limitations, such as sparsity, scalability, and black box. Many researchers have focused on sparsity and scalability problem but a little has tried to solve the black box problem. Most CF recommender systems are black boxes, providing no transparency into the working of the recommendation. This research suggests an improved CF recommender system with explanation facilities to overcome the black box problem. Explanation facilities make it possible to expose the reasoning and data behind a recommendation. Therefore, explanations provide us with a mechanism for handling errors that come with a recommendation. Furthermore, it is proposed to use web usage mining and product taxonomy to enhance the recommendation quality for e-commerce environment. For such purposes, it is developed a recommender system named WebCF-Exp(Web usage mining driven Collaborative Filtering with Explanation facilities). To test the performance of WebCF-Exp, EBIB (e-Business & Intelligence Business) research internet shopping mall and explanation interfaces are developed. Experiments are conducted with the data provided by EBIB Research Internet shopping mall. Our experiment result shows that WebCF-Exp recommendation system shows better performance than existing CF recommendation systems. And explanation with simple graph and description, showing the evaluation of similar customers, is better than other explanation types. Furthermore, the higher customer understands explanation interface, the more helpful customer purchase a product. Based on these results, an explanation facility added recommendation system is expected to be a useful tool in internet shopping malls.

### ABSTRACT

E-business portal acts as an interface between the e-suppliers and e-customers and many different types of distribution channels are defined individually by various enterprises. The logistics management and decision parameters for distribution models depend on the type of portal e.g. horizontal or vertical. In this paper the focus is on the distribution channels defined for horizontal portals, which are critical aspects of e-business but are not as explored as the other aspects. In this paper, various aspects of e-business models have been analyzed and research reveals that distribution issues need to be looked at with a fresh approach, because the traditional methods do not take into account some typical characteristics of e-business like the range of goods, transactional values and volumes the horizontal portals nowadays handle. Towards this end, three types of distribution channels for a generic horizontal portal have been identified. A decision parameter table has been formulated and used to assess various options for the distribution logistics for the horizontal portals. Also each of these broad categories has been dealt with individually highlighting their salient features along with the advantages and disadvantages associated. The primary objectives for assessment are cost savings and profit maximization of the portal. An assessment process model has been developed on the basis of some key e-business tangible parameters like transactional value, business volume etc. which can be further extended to include specific e-business model dimensions. The parameters are also analyzed subsequently in terms of their availability, size etc. so that the implementation considerations can be realistically made. Finally, the application potential, extendibility and usability of the process model have been explained and it has been shown that this generic model is simple, flexible and specific implementations can lead to e-business portals functioning with a better competitive advantage.

**Keywords:** Horizontal portals, e-business, distribution models, decision parameters, process model

### 1. INTRODUCTION

E-business: nowadays complete concept in its own, covers all aspects of a traditional business, including CRM. E-business models, like any traditional business model can be primarily conceived as a revenue-generation model, supported by the other necessary business activities like finance, marketing models etc. ([1], [8]) and it also reflects the company's position in the value chain. The models range from the simplest where a company produces a good or service and sells it to customers, to models more intricately woven, e.g. e-auctioning, brokerage, dynamic pricing or community service-based models where the value chain is not directly or obviously understood or are multi-level hybrids of other simple models.

Whatever the business models [9] are, there is a lot of research evidence about the basic fact that the web has incorporated radical paradigm shifts in the traditional business models [14] and also has given rise to new ones. The web has actually complemented or reinvented tried-and-true models, and has opened hitherto unseen revenue-earning models. [13]

#### 1.1 Various Aspects Of E-Business Models

E-business models have been defined, analyzed and categorized in many different ways and they continue to evolve. When analyzed in the context of references [1], [3] and [14], they essentially include the following aspects:

1. supply chain management
2. customer satisfaction and CRM
3. marketing
4. cost vs. quality of service

Most of the research work on the paradigm shift in e-business models is concerned about the supply chain management, customer satisfaction and CRM, and marketing ([5], [12]). The cost to quality of service aspect is one area which includes procurement and distribution logistics. Interestingly, even though traditional business models give a lot of emphasis onto these elementary aspects, research reveals that many successful e-business companies or portals are still sticking to the traditional models so far as procurement and distribution are concerned. Procurement has some research leverages as research efforts on B2B portals are coming up with interesting concepts like collaborative commerce and ERP II etc. But distribution options are still the traditional ones, which are not letting an e-business company to fully exploit its unique e-enabled infrastructure. Profitability in E-supply chains (ref. [4], [10]) includes considerations on

confidence of customer on supplier, more availability than possible in the physical world and data integrity. The first two elements are primarily dependent on the value-chain including procurement and distribution issues. This paper handles these issues relating to the distribution models of e-business portals focusing on speed of delivery and customer satisfaction which reflects the quality of service aspect, customer relationship and cost associated with distribution channels. The distribution problem for horizontal portals has been handled here and a solution process model is suggested.

## 2. PORTALS: HORIZONTAL OR VERTICAL

Horizontal portals have broad, general user base e.g. Indiatimes.com, yahoo.com etc. which are often B2C type in nature. Conversely, vertical portals serve a particular industry or a user community's supply chain, e.g. indiamart.com- the cyber-marketplace for automobile industry. For vertical portals, supply chains are mainly B2B type, quite well-defined by traditional business and can be followed in e-business as well using EDI and on bulk business. But, horizontal portals operate primarily as e-shopping malls wherein a diverse range of products of various companies are available [15]. These portals acting mostly as virtual intermediaries do not prefer intermediate physical warehouses thereby eliminating the necessity of an effective inventory management and control system. But this way, the horizontal portals have to cater to a huge range of demands of individual customers with orders of varied sizes and transactional values, raising a unique distribution problem in itself [6]. While minimizing on the cost of distribution, the customers also have to be satisfied with the speed of order fulfillment and delivery of goods [7].

The traditional mathematical foundation of distribution logistics has been operations research techniques like transportation and assignment models. But the typical characteristics of horizontal portals e.g. the huge range of transactional values, huge variations in the volume of products etc. are neither taken into account nor analyzed in these traditional methods. An attempt is made in this paper to address this particular issue. These aspects have been included in the analysis and are reflected in the set of decision parameters chosen which is elaborated in section 5. Selection amongst various available options to decide on distribution logistics is inherently dependent on the type of business models the portal uses. Following section gives a brief overview of them.

## 3. HORIZONTAL PORTAL MODELS

Some of the successful business models of the horizontal portals ([1], [8], [11]) are discussed below.

### 3.1 Direct Producer-Consumer Model

Herein, E-business removes intermediaries from the supply chain, creating a direct, efficient link between producers and consumers. A manufacturer sells directly to customers, increasing profitability while reducing consumer costs by eliminating warehouse and reseller markups. Even the primary contact for service and support also moves through online channels resulting in reduced overhead and speedy service response. Example includes lgezybuy.com [16] - a popular horizontal portal with a big range of white goods manufactured exclusively by LG. Biggest drawback is that the choices of consumers are restricted to just one manufacturer.

### 3.2 Intermediary Model

Herein, E-business introduces an intermediary for creating an E-Market- the biggest area of e-business with a great number of e-shopping malls and horizontal portals operating. Advantages include availability of options, best and competitive prices, elimination of mid-warehouses and reduction in extra costs like freight etc.

### 3.3 Customizable Models

They create investing and merchandising opportunities that were previously not available to ordinary customers. Example: baazee.com

Apart from these common models, E-business operates with various other business options too, e.g. brand-building on an e-shopping mall and integrating market segments and product segments. These businesses may or may not deliver the best possible price, but both suppliers and customers find the convenience of a single point of contact worth the exchange.

For optimal functioning of order fulfillment cycle, it is very crucial for these portals to define suitable distribution models for the products/ services they sell. If the portals' business is entirely IT-enabled and service-oriented like the airline/ railways reservation systems or accommodation booking systems etc., the supply chain is not a major issue. For example an on-line train ticket booking portal, which delivers the e-booked tickets overnight, can use any eminent courier company and take the delivery charges i.e. courier charges from the customer, which he/ she is ready to pay for the convenience of the service. But as regards the portals which sell a diverse range of goods from different manufacturers and importers, distribution becomes a crucial bottleneck in the order fulfillment cycle. In order to tackle this, there are a number of options available for the distribution models applicable which are explained in the next section.

#### 4. HORIZONTAL PORTALS: DISTRIBUTION

For portals like yahoo.com selling a huge range of goods from different manufacturers and importers, there are several distribution models available to complete the order fulfillment cycles with a defined efficiency and in a cost-effective way. These models, as perceived by the authors, are mentioned and analyzed below

**Model 1)** Customer -> Portal -> Manufacturer/importer -> manufacture/ importers' warehouse -> freight carriers(single company goods -> customer

**Advantages:**

- It eliminates mid-warehouses completely.
- Best quality product is available since company inspected goods are sent straight to customers without getting stored by dealers.

**Disadvantages:**

- It may not prove to be cost-effective
- Decision parameters have to reflect
- Relative locations of company warehouses and customer.
  - Scale of business.
  - Transactional value.
  - Product price/profitability i.e. if the profit involved can justify the freight charges or not.

**Model 2)** Customer -> Portal -> Manufacturer/importer -> manufacture/ importers' warehouse-> exclusive dealers' warehouse -> freight carriers(single company goods) -> customer

**Advantages:**

- Relative location advantages can be taken.
- Bulk handling will result in lesser freight.

**Disadvantages:**

- Dealers' commission can not be eliminated. So the company can not get maximum profit and so is unable to pass on cost savings to customers.
- Quality control can not be ensured.

**Model 3)** Customer -> Portal -> Manufacturer/importer of ordered product -> dealers handling multiple company goods-> freight carriers(multiple company goods) -> customer

**Advantages:**

- Shared distribution channels / transportation infrastructure/ shared costs is possible between companies.

**Disadvantages:**

- It can not eliminate dealers' margin.

#### 5. ASSESSMENT OF MODEL OPTIONS

Key business parameters associated with decision making for choosing a model out of the three alternative model options are identified herein as:

*T1*: Relative location of individual customers and company/ warehouses X transport cost per unit distance

*T2*: Freight charges: based on weight or volume

*T3*: Transactional value

*T4*: Cumulative historical transactional values with the customer (can be procured from historical databases/ marketing data marts)

The business parameters reflect the aspects which have been discussed in the introduction, i.e. the first two parameters *T1* and *T2* include the cost aspect, *T3* and *T4* deals with customer value which in turn reflects indirectly customer satisfaction and relationship parameters. Many other relevant parameters may be included which can be business/ context-specific and the table can be further extended.

#### 5.1 The Process Model

The assessment and decision making process is hereby developed and discussed as a process model which can later on be mapped onto an algorithm or a flow chart with more specific application orientation. In this paper the process model is developed and presented so that a generic understanding of the process can be achieved.

Process model-

**Assumptions:**

1. Weightings to parameters are to be given in the range of 0-1, i.e.  $W1 + W2 + W3 + W4 = 1$
2. All parameters are to be quantified in the same unit e.g. \$

**Steps:**

1. Calculate the Tangible Option values as follows:

$Value1 = (W1 * T1 \text{ value} + W2 * T2 \text{ value})$

$Value2 = (W3 * T3 \text{ value} + W4 * T4 \text{ value})$

2. Then

Select the best model option with (minimum of *value1* and maximum of *value2*)

3. If the Minimum ( $W1 * T1 \text{ value} + W2 * T2 \text{ value}$ ) and maximum ( $W3 * T3 \text{ value} + W4 * T4 \text{ value}$ ) do not coincide with the same option, then calculate the relative weight of *T1*, *T2*, *T3* and *T4*, i.e.  $(W1 + W2) / (W3 + W4)$

4. if  $((W1 + W2) / (W3 + W4)) > 1$ , then choose the option with Minimum( $W1 * T1 \text{ value} + W2 * T2 \text{ value}$ ), else choose the option with maximum ( $W3 * T3 \text{ value} + W4 * T4 \text{ value}$ ).

#### 6. ANALYSIS OF THE PARAMETERS

The parameters given in the assessment process are analyzed here individually in terms of the following analysis dimensions:

1. Availability of data
2. Computational complexity
3. Volume (data element size)

Table: Parameter analysis matrix

Parameters Vs Analysis dimensions	T1:	T2:	T3	T4:
Availability of data	high	high	high	High
Computational complexity	Low	Low	Low	high
Volume (data element size)	Low	Low	Low	low

From the above analysis, one important resource-related observation is made that is a data warehouse/data mart(for T4) is needed for recording transactional histories of individual customers and calculating the cumulative transactions, which reflects the level of customer loyalty and indirectly customer satisfaction also. These parameters can also be very useful for customer relationship management.

## 7. HIGHLIGHTS OF THE PROCESS MODEL

The process model analysis shows the following points:

1. A fresh approach, unbiased on the side of traditional operations research techniques is reflected in the process model which takes care of typical e-business aspects discussed in section 1.
2. This process model is flexible, can be combined with traditional logic and a hybrid solution can be developed
3. This model does not want to replace the well-researched areas of transportation and assignment problems but want to complement them by adding typical aspects of e-business.
4. This process model does not necessarily give the most optimal or cost-effective solution, but it gives a realistic and easily usable way to evaluate various options.
5. The process is simple and easy to comprehend.
6. The process can easily be converted to a computable program without any hidden conflicts. The computational requirements are also minimal and therefore the program executing this process will be highly computationally feasible i.e. processing requirements will be less.
7. It can be used by e-business organizations of any size and capabilities.

Some aspects of this process can be extended further, i.e.

1. Inclusion of other parameters exclusively applicable to any particular e-business scenario/ architecture/ company-specific requirements
2. This process only takes into account the tangible values. Intangible ones have not been included because it is a very complex process to convert them into monetary values which is not of the prevalent assumptions made in this process

## 8. CONCLUSION

The process model proposed in this paper has a realistic application potential, primarily because it is simple, understandable by any business person without any formal mathematical training i.e. knowledge of operations research techniques etc. It is also simple, therefore easy to implement and execute. Even though, it does not guarantee a perfectly optimal solution, it does address the distribution issues typical to various horizontal portals, issues that have so far been rather overlooked. In fact, vertical or B2B portals also can use this model to redefine their distribution channels, which can be more structured and standardized than horizontal ones. The extension possibilities are great as the model is simple, flexible, scalable and can be modified easily to suit specific business/ context requirements.

Coming out of the traditional mindset in dealing with this type of issues, and embracing new ideas and innovations generated in any of the basic infrastructural aspects would be capable of making e-business environment all the more competitive. Such efforts will also allow the new business models exploit their newness in all possible ways by considering all its'aspects with fresh approaches.

## ABSTRACT

With merchant information increasing rapidly, customers have to spend a lot of time and energies to search for goods they need, as a result, they maybe find nothing. If merchant can respond customer's requirements agilely when the event defined by customer appears, blindness of customer can be avoided, merchant wins business opportunities too. Protocol is the technology fundament for e-commerce. An idea for agile mechanism is introduced, this paper designs an e-commerce protocol with agility, and it discusses its security. This protocol improves e-commerce efficiency and solves activity problems.

**Keywords:** e-commerce, protocol, agility, E-P executing model

## 1. INTRODUCTION

Higher efficiency and lower cost of e-commerce makes more and more companies take part in this business mode. Without e-commerce, enterprise can not participate in global challenge on business, it not only changes enterprise mode of product, operation and management, but also influences economic operating of society entirely<sup>[1]</sup>. However, development of e-commerce is influenced by informative fundament, security payment, credit system, delivery link and law environment. When customers roam in vast Internet sea to search goods they need, they have to spend a lot of time and energy, as a result, they maybe find nothing. Much overflow information makes e-commerce become lower efficiency and not meet rapidly enterprise application. How to reverse the positive situation to make e-commerce serve enterprise agilely?

Protocol is support technology to guarantee e-commerce security, transaction and application. Many protocols can be concluded three varieties; they are security protocol, transaction protocol and special application protocol. Summarizing these protocols, each does as he likes. Netbill protocol only is used for digital goods sales. SET has more than 3000 lines grammar definition, 28 steps transaction, each step has 6 times RSA. Digicash pays by means of digital cash, because of its uniqueness, it has the same anonymous and non-traceable features as digital cash. The core of Digicash is blind signature<sup>[2]</sup>. TLS (Transport Layer Security), IPSEC and PPTP, variation of SSL, are transmitting control protocols over TCP/IP<sup>[3]</sup>. Either these protocols are too easy and only can meet some special application, or they are too complicate and lead to lower efficiency and a large expense. They are considered insufficiently in customer requirement, perfection and intelligence, such as lacking credit, negotiation, active service and multi-medium payment.

Protocol is not designed perfectly so that customers

undergo much suffering of overflow information. This paper researches on aspect of business agility; it introduces agile mechanism and makes protocol have agile property.

## 2. AGILE E-COMMERCE SYSTEM

### 2.1 Conception on Agility

Let's see an instance for e-commerce, when a customer accesses a merchant web site to buy something, being out of stock, it can not meets customer this time, when the customer comes here next time, it is maybe short yet, but between the two times, perhaps the commodities are in there and sold out again. In this case, it is possible that customer loses the chance not to obtain goods he needs in the end, as a result, customer waste a lot of time, merchant loses business chance too. If merchant can inform customer actively in replenishing stock, this problem can be solved better. This case demands e-commerce system have an ability to serve customer actively, the system is agile. Agility means it executes transaction automatically to finish business activity in coming definition event.

### 2.2 E-P Executing Model

Following gives E-P executing model for agility mechanism.

Event Definition : Events causing agile service consist of different kind of events.

$$E = \{p_t(o) \in (E_t, E_e, E_c, E_u) | o \in D_T \wedge p \in p(o)\}$$

Where  $E$  stands for event set relating to transaction  $t$ ,  $p_t(o)$  stands for the event which transaction  $t$  executes operating  $p$  on object  $o$ ,  $D_t$  is data set of  $t$ ,  $p(o)$  is operating set of  $o$ ,  $E_t$ ,  $E_e$ ,  $E_c$ ,  $E_u$  respectively stands for time event, external event, complex event and user-defined event.

**Transaction Definition :** Transaction set deposits a series triggered transaction, which corresponded with different event.

$$T = \{p(o) | \exists o \exists p(o) \in (T_s, T_c, T_m \dots)\}$$

Where  $T_s$ ,  $T_c$  and  $T_m$  respectively represent system transaction, customer transaction and merchant transaction.

**Trigger Definition :** Trigger is a dual series of condition and triggered transaction.

$$R = \{Cond, T\}$$

Where *Cond* and *T* respectively stand for condition and triggered transaction.

**Agility Mechanism :** Agility mechanism is a mate of event and process.

$$A = \{ \langle e, p \rangle | e \in E, p \in P, P = \langle CD, R, TMG \rangle \}$$

This is *E-P* model. *CD* is event detector, process *P* is a triple set, and *TMG* is transaction management program.

How to create an agile e-commerce system? Using *E-A* model on active database by means of document [4], when merchant system can not meet the customer's requirement, it allows customer define events and monitor it in real time, once the defined event appears, condition detector sends message to trigger management program, it evaluates the condition and requests *TMG* creating a transaction and executes it, so that it can realize the agile service function of merchant system. Figure 1 is the e-commerce system with agile ability.

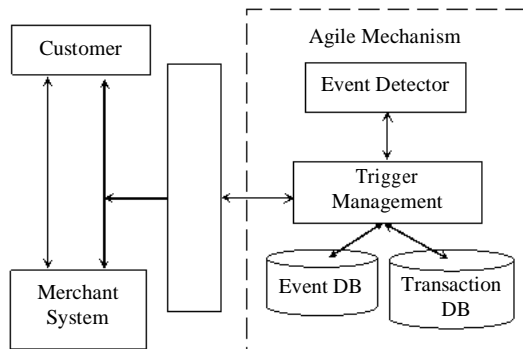

Figure 1 E-commerce system with agile ability

### 3. PROTOCOL DESIGN

#### 3.1 Symbol

*E* : Entity.  $E \in \{C, M, T, B\}$ , *C*, *M*, *T* and *B* respectively stand for customer, merchant, TTP(Trusted Third Part) and payment gateway.

$A|B$  : It is entity object.  $A|B \in \{C, M, P\}$ , *C*, *M* and *P* respectively stand for customer, merchant and payment gateway.

*Req* : It is goods information that is searched.

$A?B:(X)$  : It is that entity *A* ask entity *B* about information *X*.

$X+Y$  : It is link of message *X* and message *Y*.

$X, Y$  : It is series of message *X* and message *Y*.

$A"B:(X)$  : It is that entity *A* send message *X* to entity *B*.

$Prg.Opt[(Obj)]$  : It is that procedure *Prg* executes operation *Opt*. *Obj* is operation object.  $Prg \in \{CD, R, TMG\}$ .

$D_{ASK}(X)$  : It is signature to message *X* with secret key *ASK* of entity *A*.

$E_{BPK}(X)$  : It is encryption to message *X* with public key *BPK* of entity *B*.

$H(X)$  : It is abstract of message *X*, *H* is strongly one-sided Hash function.

*OI* : It is order information.  $OI = (GName, GType, GNumber, dod)$ , *GName*, *GType*, *GNumber* and *dod* respectively stand for goods name, specification, amount and date of delivery.

*GDB* : It is merchant database.

*CertE* : It is certificate of entity *E*.

*PI* : It is payment information.  $PI = \langle CAN, PW \rangle$

*CAN* : It is customer account.

*PW* : It is password of customer account.

*MAN* : It is merchant account.

*receipt* : It is merchant receipt.

*CID* : It is customer identity.

#### 3.2 PROTOCOL DESCRIPTION

It is provided *C*, *M*, *T* and *P* have had verified certificate. *C*, *M* and *B* have registered from *T*, *M* has conserved the copy of certificate of *T*, *T* has conserved the copy of certificate of *B*. *T* acts as certificate, notarization, payment, arbitrate and time postmark in e-commerce protocol<sup>[5]</sup>, *T* plays the role of identity verifying, payment and evidence-protected in this protocol. This protocol consists of two sub-protocol, they are marked as Agility and Business. Generally, it executes Business protocol, Agility protocol is executed when merchant do not meet customer requirements.

##### Business :

$B1 : C^M : (E_{MPK}(D_{CSK}(OI, Cert_t), H(OI)))$ , *C* sends order information by way of signature to *M*.

$B2 : M$  decrypts the message with secret key *MSK*, and decrypts *OI* and *Cert<sub>t</sub>* with secret key *CSK* sent by *C*, and verifies truth of order information and identity of *C*.

$B3 : M^C : (E_{CPK}(D_{MSK}(Cert_M, Cert_t, PI))$ , *M* submits signature certificates of *M* and *T* and request payment information to *C*, certificate of *T* is preserved by *M* in advance.

$B4 : C$  decrypts the message with secret key *CSK*, and verifies certificates of *M* and *T* with secret key *MSK* sent by *M*.

$B5 : C^M : (OP, CM, CT)$ ,  $OP = H(OI) + H(PI)$ ,  $CM = E_{MPK}(D_{CSK}(OI, H(PI)))$ ,  $CT = E_{TPK}(D_{CSK}(PI, H(OI)))$ , *C* sends payment information by way of dual signature to

*M*.

B6 : *M* decrypts *CM* with secret key *MSK*, and decrypts it again with secret key *CSK* sent by *C*, *OI* and *H(PI)* are obtained, then  $OI' = H(OI)$ ,  $OP' = OI' + H(PI)$ .

B7 : It creates  $H(OP)$  and  $H(OP')$  to verify their consistency, and compares them whether they are equal, if they are equal, it manifests *OI* is the order information related to *PI*, if not, it demands *C* send message again or cancel it.

B8 :  $M^*T:(OP, CT, KI)$ ,  $KI = E_{TPK}(D_{MSK}(MAN, Cert_M, Cert_C, dod))$ , *M* sends request payment information by way of dual signature to *T*.

B9 : *T* decrypts *CT* and *KI* with secret key *TSK*, and decrypts it again with secret key *MSK* sent by *M*, *PI*,  $H(OI)$  and certificates of *M* and *C*, then  $PI' = H(PI)$ ,  $OP' = H(OI) + PI'$ .

B10 : It creates  $H(OP)$  and  $H(OP')$  to verify their consistency, and compares them whether they are equal, if they are equal, it manifests *PI* is the payment information related to *OI*, if not, it demands *M* send message again or cancel payment.

B11 : Prepayment. *T* transfers *pm* to *MAN* from *CAN*, and sends successful message *prepaid* to *M*.  $T^*M: E_{MPK}(prepaid)$ .

B12 : *M* decrypts it with secret key *MSK*, then sends payment time *dop* to *C*,  $M^*C: E_{CPK}(dop)$ ,  $dop < dod$ .

B13 : *C* decrypts it with secret key *CSK*, then  $C^*M: E_{MPK}(agreement)$ , *C* agrees to the payment time.

B14 : *M* decrypts it with secret key *MSK* and gets message *agreement*, then merchant delivers goods to customer, and sends receipt to *T*,  $M^*T: E_{TPK}(D_{MSK}(receipt, H(Cert_M)))$ .

B15 : Customer receives goods and verifies it is no problem, and sends message to *C*,  $C^*T: E_{TPK}(D_{CSK}(H(Cert_C)))$ .

B16 :

(1) *T* decrypts them and gets message *receipt* and  $H(Cert_C)$ , and verifies identification of *M* and *C*, then sends payment information to payment gateway *B*,  $T^*B: E_{BPK}(D_{TSK}(PI, pm, MAN, Cert_T, H(Cert_T)))$ ,  $Cert_T$  is conserved in *T* when merchant registers.

(2) *T* has only received message *receipt* from *M*, and verified identity of *M* is legitimate, or received unreal identity message from *C*, when payment time *dop* comes, *T* send payment request to *B*.

(3) *T* has only received message  $H(Cert_C)$  from *C*, and verified identity of *C* is legitimate, *T* send payment request to *B*.

(4) *T* has not received any message within *dod*, it cancels payment automatically and informs *M* and *C*.

B17 : *B* decrypts message from *T* with its secret key *BSK*, and verifies signature identity of *T* with secret key sent by *T*, *B* formally transfers *pm* to *MAN* from *CAN*.

B18 : *B* returns successful message *success* of payment,  $B^*T: E_{TPK}(success)$ .

B19 : *T* decrypts *success*,  $T^*C: E_{CPK}(finish)$ ,  $T^*M: E_{MPK}(finish)$ , *T* sends finished message to *C* and *M*.

### Agility:

A1 :  $C^*M:(Req)$ . *C* inquires *M* for *Req*.

A2 : If *M* has *Req*, then  $C^*M:(E_{MPK}(D_{CSK}(CID, H(CID), OI)))$ ,  $OI = (GName, GType, GNumber, dod)$ , *GName*, *GType*, *GNumber* and *dod* respectively stand for goods name, specification, amount and delivery of date. *C* sends message with signature and encryption to *M*.

A3 : *M* decrypts message with its secret key *MSK*, then verifies identity of *C* with the secret key *CSK* sent by *C* according to  $H'(CID) = H(CID)$ .

A4 : Define  $E_u$ (Have *GName* in *GDB*), *M* defines event  $E_u$ .

A5 : *CD.Start*, Event detector *CD* starts.

A6 : *CD.Scan(GDB)*, *CD* scans *GDB*.

A7 :  $CD^*R:(E_{MPK}(E_u \text{ arises}))$ , When defined event appears, *CD* sends the message to trigger management program *R*.

A8 : *Evaluate Cond(GType, GNumber, dod)*, Trigger management program *R* evaluates condition.

A9 : *R.Activate(TMg)*, *R* activates *TMG* when condition is given.

A10 : *TMG.Create(t)*, *TMG* creates relative transaction *t* and executes it.

A11 :  $M^*C:(E_{CPK}(OI))$ , *M* sends message *OI* to *C*.

A12 : *C* decrypts message *OI* with its secret key *CSK* and obtains the order information. The protocol is end till now.

### 3.3 ATOMICITY AND SECURITY

Protocol should meet atomicity of money, goods and affirmable message<sup>[6]</sup>. Known from B11 and B17, decrease of customer fund is increase of merchant fund, so it conforms to atomicity of money. Prepayment at step B11 meets both atomicity of money and preventing deceit deed of merchant and customer. Known from B15 and B16, customer begins to pay while he gets goods. Known from B14, B16 and B17, merchant deliveries goods while he receives payment money, so deed which customer gets goods without payment or merchant receives payment without delivery is not happened. This way of payment in getting goods conforms to atomicity of goods. Known from B14, B15 and B16, *TTP* asks payment gateway for payment and preserves transaction evidence when *TTP* has received receipt of merchant and identity message consent to pay by customer, this realizes atomicity of message who send it.

Truth to identity of transaction entity is important guarantee of protocol security. Certificate is the legal mark of identity, entities apply certificate authority for certificate. It needs to identify the truth of identity through delivering certificate in transaction entities. There is six times identification among four entities, *C* and *M*, *C* and *T* verify each other, and certificates of *T* and *B* are respectively conserved in *M* and *T* in advance, so *T* only needs to verify identity of *M*, *B* only needs to

verify identity of  $T$ . Process to identification consists of B1, B3, B8 and B16. Figure 2 shows the process.

Figure 2 Identification process

Before formal payment,  $T$  needs to verify identity consistency of  $M$  and  $C$ . Certificates of  $M$  and  $C$  are sent to  $T$  at step B8,  $H(Cert_M)$  and  $H(Cert_C)$  are created,  $T$  compares them to these sent through B14 and B15, if they are equal, it shows identity of  $M$  and  $C$  are consistent and true.

Deceit means  $M$  gets  $C$  money by cheating without delivering goods or  $C$  gets goods without payment. To prevent deceit is one of security problems for e-commerce protocol. Obviously, deceit deed may happen in period of Business protocol.  $M$  may send a false receipt to  $T$  without delivering goods when protocol executes step B14,  $C$  does not send its certificate or send a false certificate to  $T$  when protocol executes B15. Considering success or failure of communication, there may have nine kinds of situations when protocol executes.

(1)  $M$  and  $C$  are both honest, they send message to  $T$  successfully.

(2)  $M$  and  $C$  are both honest,  $M$  sends message to  $T$  successfully, and  $C$  is failure.

(3)  $M$  is honest,  $C$  is deceitful, they send message to  $T$  successfully.

(4)  $M$  is honest,  $C$  is deceitful,  $M$  sends message to  $T$  successfully,  $C$  does not send message to  $T$ .

(5)  $M$  and  $C$  are both honest,  $M$  fails to send message to  $T$ , and  $C$  is successful.

(6)  $M$  and  $C$  are both honest,  $M$  and  $C$  fail to send message to  $T$ .

(7)  $M$  is honest,  $C$  is deceitful,  $M$  fails to send message to  $T$ ,  $C$  does not send message to  $T$ .

(8)  $M$  is honest,  $C$  is deceitful,  $M$  and  $C$  fail to send message to  $T$ .

(9)  $M$  is deceitful and sends message to  $T$  successfully.

Step B16 can solve above-mentioned problems. For situation (1), step B16(1) solves it, step B16(2) solves situation (2), (3) and (4), step B16(3) solves situation (5), step B16(4) solves situation (6), (7) and (8).

TTP is an entity of prepayment, it preserves certificates of  $M$  and  $C$  and transaction information as evidence at the same time. Responsibility in protocol executing is traceable, it resists denying. For situation (9),  $M$

deceives successfully, that is to say,  $M$  sends a false receipt to  $T$ ,  $T$  pays only when signature certificate of  $M$ . If  $C$  does not get goods when  $dod$  expires, it can find out  $M$  is to blame.

#### 4. CONCLUDING REMARKS

E-commerce protocol with agility can handle customer active request in real time, it makes merchant e-commerce system respond to a customer request agilely, and changes positive e-commerce into active e-commerce, and wins more opportunities for merchant.

Security to e-commerce includes three layers, they are physical layer, data layer and business layer. This protocol bases on business application layer. Signature guarantees security of business information. MD5 is a kind of common Hash to signature. Found by Wang Xiaoyun, MD5 exists "conflict", two files can create the same finger mark, this discovery makes law effect of current signature challenged<sup>[7]</sup>. Universal used signature algorithm in e-commerce is worth to research.

Agent technology becomes more and more mature, it has wide prospect in e-commerce. Protocol introduced here is only tentative program, it does not introduce the content of intelligence search, negotiation, transaction agent and so on, and these valuable tasks are worth to study for us.

### ABSTRACT

This paper describes research supporting the development of a conceptual model for understanding the sources of business value of Business-to-Business (B2B) Electronic Markets. Based on six case studies and an analysis of current literature, Aggregation, Matching, and Integration emerged as the three key sources of business value. The framework provides a structured and systematic approach for understanding various B2B Electronic Market models, and helps develop strategies to leverage these sources of business value.

**Keywords:** Electronic Markets, Business-to-Business Electronic Commerce, Business Value of IT

### 1. INTRODUCTION

In the wake of the Dotcom crash in 2000, interest in Business-to-Business (B2B) Electronic Markets have waned. Nevertheless, this should not be interpreted as a failure of the Electronic Market model in gaining traction amongst organizations and industries. On the contrary, Electronic Markets such as ChemConnect, Exostar and TheSeam.com have transacted millions, if not billions of dollars worth of transactions in the post-Dotcom days. In 2002, ChemConnect facilitated \$8.8 billion worth of transactions, penetrating up to 44% of the chemical industry players [1]. As Wise and Morrison argued, whilst the benefits of Electronic Markets are clear, the path to achieving them is anything but [2].

This paper describes the development of the conceptual model, using empirical data from six case studies, and an analysis of existing literature on Electronic Markets. The empirical data and literature analysis suggest *Aggregation*, *Matching*, and *Integration* are the three principal sources of business value associated with Electronic Markets. Aggregation, Matching and Integration are then lined-up against a series of business processes that typically underpins inter-organizational electronic commerce – (i) Information Gathering, (ii) Supplier Contact, (iii) Background Review, (iv) Negotiation, (v) Fulfilment, (vi) Consumption, maintenance and disposal, and (vii) Renewal [3].

### 2. CONCEPTUAL FRAMEWORK

Bakos defines Electronic Markets as Inter-Organizational Systems (IOS) that facilitate participating buyers and sellers to exchange information about prices and product offerings [4]. Many modern web-based Electronic Markets have evolved from intra-organizational database systems, simple electronic

distribution channels and electronic bulletin boards, such as TELCOT [5], ASAP [6, 7], and SABRE [8, 9], into complex Electronic Market systems that support a whole range of products and processes.

Current literature on Electronic Markets concentrates on the types of products and industries which have adopted Electronic Markets [10, 11] and the effects of adoption [9, 12, 13]. Kaplan and Sawhney proposed a framework for categorizing Electronic Markets according to the nature of transactions – spot vs. systematic purchases, and the types of products transacted – direct vs. indirect supplies [13]. Choudhury et al. and Lee evaluated in [10] and [12] respectively, the effects of Electronic Markets on product prices, and found no conclusive evidence to suggest that Electronic Markets lowered the prices of products. The effect of Electronic Markets on inventory levels was also examined in [12]. Again, minimal effects were observed.

Malone et al. regarded Electronic Markets as a structure that governs inter-organizational relationships according to the Transaction Cost Theory [14], asserting that the use of information technology will lead to a shift toward markets from hierarchies. Using a micro-economics approach, Bakos asserts that by reducing the search costs involved in inter-organizational trade, Electronic Markets increase market efficiency [4]. Taking a multi-disciplinary approach, Amit and Zott provided a holistic overview of various theoretical approaches towards the issue of business value of Electronic Business [15]. This study seeks to understand “how” and “why” organizations derive business value through an analysis of the sources of business value. While there are numerous sources of business value, the present study examines the three principal sources which have emerged from the case studies and analysis of literature.

Aggregation, Matching, and Integration have been identified as important in Electronic Markets [13, 16, 17]. The model developed in this study incorporates these three themes, using them to analyze and evaluate the activities supported by Electronic Markets. This study does not intend to test or prove the causality between Electronic Market adoption and the derivation of business value. Instead, it explores contemporary themes in Electronic Markets [2, 18].

### 3. METHODOLOGY

The objective of this study is to discover a better means of understanding how organizations benefit from engaging in B2B Electronic Markets and to enable this through a formal framework. Following the method prescribed by Yin [19] and Stake [20], data was collected from six case studies. A qualitative approach was adopted for this study to gain the rich data that emerges from in-depth studies [21]. Semi-structured interviews were conducted with 16 executives who were actively involved in the Electronic Market operations. Outcome from the interviews was matched with the findings from existing literature to form the conceptual model. The following is a summary of the six case studies conducted:

#### Case One

The organization involved is a finance-oriented company<sup>1</sup>. It is a subsidiary of a multinational company located in the US. The organization uses online reverse auctions to source indirect supplies for its various business units. A sample of some of the indirect supplies it has sourced via reverse auctions [22] includes office supplies, accommodation, cleaning and courier services. The organization engages in reverse auctions with the objective of improving the supplier bidding process, increasing competition among the suppliers, and pooling together purchases for its different business units.

#### Case Two

This case involves an organization which set up an Electronic Market that catered for life science supplies. Members of the Electronic Market are able to buy and sell from that market. The sellers are mainly firms producing or retailing chemicals and apparatus, while the buyers are private laboratories and government agencies. At times, organizations that sell on the Electronic Market also buy from it. The organization that owned the Electronic Market had future plans to create new Electronic Markets in other industries.

#### Case Three

This case surrounds an Electronic Market for steel supplies. The steel Electronic Market caters especially for the Asia-Pacific region. The highly segmented steel

supplies industry in this region provided a great opportunity for the Electronic Market to link up with many smaller-sized steel suppliers that are geographically distributed. The Electronic Market for steel provided additional value-adding services, such as insurance, finance, freight and forwarding services to buyers and sellers. The concept was to provide a one-stop service for both buyers and sellers, which are made up of many small and medium businesses, which otherwise would not participate in Electronic Markets.

#### Case Four

The organization represents a branch of a leading computer component manufacturer. It uses an extranet system to coordinate with its distributors. The distributors are able to place their orders on the extranet and check on component availability. The extranet is extremely useful in streamlining the distribution chain in shortening the business cycle time, which is especially important in the computer component industry where obsolescence is costly and minimal inventories are kept. The extranet system allows the component manufacturer to gain access to real-time market information, and adjust its production capacity accordingly.

#### Case Five

This case involves an Electronic Market that was set up by a telecommunications organization for indirect supplies. The electronic market is targeted at its trading partners. It is aimed at creating an online community of organizations which could share each other's contact, increasing business between members of the community. Some of the goods and services which have been traded on the Electronic Market include office supplies, furniture, hotel accommodation and office equipment maintenance services.

#### Case Six

The organization involved represents a major healthcare product supplier. It maintains an online catalogue of healthcare products, such as hospital supplies, diagnosis machineries and equipment. The buyers are made up of hospitals, clinics, laboratories and specialized healthcare providers. This healthcare product supplier maintains close relationship with the major healthcare product manufacturers, and as such, operated as an intermediary between the manufacturers and the buyers. Buyers are able to place orders and check on delivery status electronically. Invoicing and electronic payments have been enabled with selected customers.

### 4. DEVELOPING THE CONCEPTUAL FRAMEWORK

Three steps were involved in the development of the conceptual model.

Step One involved identifying the three main sources of business value. The aim of this first step is to categorize

<sup>1</sup> Names of the companies are omitted at their request because of commercial considerations.

the different sources of business value which are relevant to B2B Electronic Markets. It is important to keep in mind that this study does not intend to test the strength and causality of Electronic Markets adoption and the derivation of business value. The purpose is to suggest the sources of business value based on themes which emerged from the six case studies. The cases were chosen from a variety of Electronic Markets from different industries to avoid the results from being limited to one form of marketplace only.

Step Two involved identifying the business processes facilitated by Electronic Markets. There are several ways for viewing the various business processes involved in a typical business transaction. For the purpose of this study, the Business Procurement Life Cycle model [3] was adopted. The seven stages of the business processes are: (i) Information gathering, (ii) Supplier contact, (iii) Background review, (iv) Negotiation, (v) Fulfilment, (vi) Consumption, maintenance, disposal, and (vii) Renewal. The objective of identifying these seven business process stages is so that the sources of business value can be studied depending on the business process it influences.

Step Three involved identifying the stakeholders. This final step involves identifying the stakeholders, so that the sources of business value can be specified and evaluated from different perspectives. The sources of business value may take on different meanings depending on the role of the stakeholder in the Electronic Market. Ideally, Electronic Markets create win-win situations for buyers and sellers. The parameters identified in Steps One, Two, and Three are then combined into a grid where the business processes are represented by rows, and the sources of business value, as viewed from different stakeholder perspectives, are represented by columns. It should be noted that there are numerous sources of business value that could be considered, and this study is by no means exhaustive in suggesting Aggregation, Matching, and Integration as the main ones. Rather, they appear to be the ones most relevant to B2B electronic markets.

## 5. DISCUSSION

The three significant themes which have emerged from the six case studies suggest their importance in the development of an analytic framework for B2B Electronic Markets. The indirect material procurement Electronic Market in Case Five demonstrated how the organization in question shared its business contacts with its trading partners, including allowing the trading partners to enjoy discounts and superior contractual terms that the organization has already negotiated with its suppliers. The pooling of this resource was used to encourage greater trading volume, creating a win-win situation for all the members of Electronic Market.

Stakeholders with similar interests pool their purchasing

power, resources and expertise via Electronic Markets. Aggregation is not new. It had occurred prior to the availability of Electronic Markets, for example, co-operatives were formed to help their members buy and sell, but with Electronic Markets, aggregation has further encouraged organizations to pool purchasing power, resources and expertise across geographical and temporal barriers. Aggregation is especially beneficial to smaller-sized organizations, which by themselves have too little influence and negotiating power. Aggregation is useful to the bigger organizations as it allows them to share their expertise with their trading partners, creating a closely-knit Electronic Market community.

The second theme which emerged from the six cases was that Electronic Markets enable buyers and sellers to seek out each other with greater ease. Electronic Markets often allow stakeholders to gain access to new market segments. The Electronic Market may also create a whole new market-space, playing the role of an intermediary. In the case of the steel Electronic Market in Case Three, it has opened up what was previously a highly segmented market. In a crowded market-space that has stakeholders with varying IT capabilities, the steel Electronic Market gave them access to the international steel market. The stakeholders were able to gain information about potential trading partners with minimal effort in advertising and tendering. Equipped with the information, buyers and sellers were able to find trading partners that could meet their requirements. This theme suggests that Electronic Markets may improve a market's efficiency, in that they link up sellers with buyers, reducing the effort of both parties in searching for each other.

Apart from enabling organizations to access new trading partners, it was also found that Electronic Markets allow existing trading partners to seek out new opportunities within existing trading relationships. As observed in Case Six, the healthcare product supplier was able to sell more types of products to existing customers. The online catalogue provided rich information on a huge range of products. The online catalogue is also capable of informing buyers of alternative products. If a required item is not available, then the online catalogue suggests the closest substitute. Were it not for such information on alternative products, the customer could have easily taken its business elsewhere.

In the case of the reverse auctions in Case One, it was observed that a bidder for a contract to supply services to the organization in question in a particular city was able to bid simultaneously for similar contracts to supply an organization in another city. Suppliers were able to seek out new business opportunities with existing trading partners via Electronic Markets. This is due to the fact that the reverse auction tendering system allows the organization to gain access to a greater number of bidders with marginal effort. Electronic

Markets enhance information exchange and sharing within a trusted business community, allowing buyers and sellers with specialized requirements and skills to seek out each other. As suggested by the channel manager of the extranet in Case Four, the Electronic Market system enables his organization to micro-market, gaining access to niche markets, to the extent of creating market segments which have only one customer. For sellers, Electronic Markets enable them to sell to buyers of highly customized goods. For buyers, Electronic Markets give them access to a bigger supply base capable of meeting their demand for customized goods. The organization in Case Four benefited from gaining up-to-date market information from its extranet. Customer orders determine the operations of the supplier, resulting in fewer inventories held. As such, the organization was more agile and flexible and could respond to changes in the market quickly.

The third theme which emerged from the cases relates to Electronic Markets enabling organizations to synchronize their business processes, improving coordination and collaboration with trading partners.

This idea of coordination and collaboration between organizations is not entirely new either. The Supply Chain Management concept describes how members of a supply chain share inventory and logistical data. In the Electronic Markets era, however, Integration relates to the synchronization of inter-organizational processes

that occur at the pre-transaction and the post-transaction stages. Electronic Markets can be used at the product development and design. Manufacturers can collaborate with suppliers via Electronic Markets to jointly develop products, while constantly receiving feedback from customers. The information shared among organizations may include those used for project management, product testing, and customer feedback and market research.

In Case Three, the steel Electronic Market provided facilities for insurance, finance, freight, and forwarding facilities to buyers and sellers. The Electronic Market is not limited to providing order-processing and invoicing facilities. Integration was demonstrated in Case One, where that organization used the Electronic Market to integrate its tendering and bidding processes. Although reverse auctions were mostly used for sourcing new supplies, the organization involved has even used reverse auctions to tender out contracts for the maintenance and disposal of computers and peripherals.

This illustrated how Electronic Markets integrate business processes at the post-transaction stages. Electronic Markets, it appears then, can function beyond supporting order-processing, invoicing, and logistics-related business processes. Table 1 below summarizes Aggregation, Matching, and Integration, as the emerging themes from the six case studies.

Table 1: Summary of case studies and emerging themes

Case Study	<i><b>AGGREGATION</b></i>	<i><b>MATCHING</b></i>	<i><b>INTEGRATION</b></i>
<b>Finance Organization Reverse Auctions</b>	Aggregating demand (pooling of purchases)	Electronic bidding for price discovery and determination	Integrating tendering & bidding processes
<b>Life science Electronic Market</b>	Aggregating demand and supply	Accessing new market segments, accessing new trading partners	Integrating tendering & bidding processes
<b>Steel Electronic Market</b>	Aggregating demand and supply	Accessing segmented market, accessing geographically distributed trading partners	Integrating freight, forwarding, insurance, payments
<b>Electronic Distribution Channel</b>	Little evidence	Sharing of time-critical market information	Integrating inventory management
<b>Indirect Supplies Electronic Market</b>	Aggregating demand and supply	Accessing new trading partners, leveraging existing trading partners for new sales opportunities	Little evidence
<b>Healthcare Products Online Catalogue</b>	Aggregating supply	Acting as an intermediary, allowing customers to access many trading partners	Integrating order-placing, invoicing, logistical processes

Data gleaned from the six case studies indicates that a particular source of business value influences different organizations at different business process stages. A possible explanation is that these Electronic Markets had different objectives, for example, the reverse auctions in Case One was a complementary procurement channel, whereas the life science Electronic Market in Case Two represented a new platform that brings together buyers and sellers within a market segment. At different stages of implementation

of Electronic Markets, the emphasis on the source of business value may vary also, e.g. new Electronic Markets concentrate on Aggregation, whereas established Electronic Markets concentrate on Integration.

## 6. CONCLUSION

The B2B Electronic Markets arena is still evolving. Economic rationalization brought about a survival of the

fittest scenario for Electronic Markets. Successful ones like ChemConnect and Exostar are gaining momentum while unsuccessful ones like Chemdex have faltered. A lot remains to be understood about the strategies underpinning successful Electronic Markets. While past research concentrated on the impact of information technology on business processes such as negotiation and fulfilment, this study demonstrated a framework that emphasizes how B2B Electronic Markets influence business processes such as information gathering, supplier contact, and consumption, maintenance and disposal. This is important as the benefits of Electronic Markets are not restricted to price and cost reductions. Inevitably those outcomes are a function of business process and any value generated in business process optimization.

The adoption of the proposed model for analyzing Electronic Markets-related problems or analysis of Electronic Market strategy by businesses will aid identification of value and formulate strategies based on real exemplars. Contributions of this study to an understanding of B2B Electronic Markets include that it: presents a structured way of understanding the benefits of Electronic Markets; helps identify future areas of opportunity; enables the analyst or business manager to view the business value from different stakeholder perspectives; enables researchers and practitioners to analyze and formulate strategies for Electronic Markets; provides propositions for future research; and enables the use of the model to analyze published cases of Electronic Markets.

# Benefit Evaluation Model of E-Government Procurement

Mingzhu Jin, Xuping Jiang

School of Economic and Management, Tsinghua University, Beijing 100084, China  
{Jinmzh, Jiangxp}@em.tsinghua.edu.cn

## ABSTRACT

Since 1990s, Information Technology has developed at speed. With the development of IT and Internet, E-Government affair has become the focus of every government. As an important part of E-Government Affair, E-Government Procurement has a great influence on the development of economy. Based on the situation of Government Procurement of China, this paper states the importance of benefit evaluation of government procurement, and attempts to build up the benefit evaluation system model of Government Procurement in China, separately from economic benefit, political benefit and social benefit. Further more, some criteria for the information collection of E-government Procurement will be summarized.

**Keywords:** E-Government; E-Government Procurement; Government Procurement Agreement (GPA); WTO; Benefit Evaluation System; criteria system; Analytic Hierarchy Process (AHP)

## 1. INTRODUCTION

E-government is a kind of application information system realized by information technology, which is used to serve the detailed business, transaction, and conference of government. It is on the basis of the substantial government organization and resources in the Internet. Concretely speaking, E-government is a kind of behavior pattern of government depending on the Internet, which is closely related to the government management and society business service.

E-government is the result of Information Technology Revolution. In the face of the challenge of IT and Information Society, E-government development has become the focus of every country in the world. As result, the efficiency of government and service quality is improved by IT, at the same time the competitive power of the country is increased greatly to be against the challenge of Information Society through E-government. At present, E-government development are accelerated in all the countries in the world, which is not only important to improve the efficiency of government affairs and public service, but also especially important to improve the transparency and democratization of government.

Until to 2003, all office business has been put on the Internet in American Federation Institutes and Singapore government; government of Japan launched the project "new era" in February, 2000 and planed to perform all the government business during the period from 2003 to 2005; until 2002, 41% of citizens in U.K. were served mainly by the website of government institutes of U.K.

According to the report of world economic forum: the maturity degree of E-Government in China is 23%, which is still in the stage of building the basic frame. Three kinds of information system of E-Government

have been set up in our country: office system network among government departments; information sharing and real time online communication between all the functional government departments; information dual-communication between the government and citizens through the Internet. Some foreign academic institutions have put forward some evaluation standards for E-government, but in China there is still not a uniform, scientific evaluation criteria system for E-government, which draws attention of the academicians in China.

## 2. OVERVIEW OF GOVERNMENT PROCUREMENT

As one important part of the E-Government system, government procurement is the key node of public financial system, which is one of basic methods by which financial management and payment of the government is carried on under market economy system. According to government procurement agreement (GPA) in WTO, government procurement is defined as: the purchase and lease of the goods, service, projects of the central government and sub-government of member countries in WTO, and foundation of public facilities. Generally speaking, the procurement of central government takes on about 10-15% of GDP.

From 1990s on, with the development of IT and popularization of the Internet, government procurement on the Internet has become one of the main parts of government procurement revolution in many countries. The advantages of E-procurement are shown below:

- a. Time saving. During the whole E-procurement process, time is greatly reduced and procurement efficiency is greatly improved.
- b. Cost cutting. During the E-procurement, almost all the payment on the printing and posting can be saved, and workload is reduced, so that the cost of procurement is greatly

- reduced.
- c. "Open, justness, justice" principle sufficiently sticking to. The reduction of information asymmetry and corruption can make competition in government procurement market more sufficient and closer to "business in the sunlight".
- d. Effective and active government impression shaping. With the application of modern network in E-procurement, government shows aggressive and revolutionary spirit, which strengthens the belief of the citizens to government as result.

In China, government procurement is still a new thing. In the middle of 1990s, some provinces in China began to test the government procurement reformation, and it is Shanghai city that was first to try the reformation, and it is Shenzhen city that was first to set up the regional law for government procurement.

At present, government procurement is in the process of change from primary phase to entirely developing phase. In 2002, government procurement was supported by all levels of governments and parties, and received great achievement that the total procurement broke through 100 billion RMB, 100.96 billion. According to the statistic data from 37 provinces, the target of government procurement is 113.54 billion RMB in 2002, and the real payment is actually 100.96 billion, the cash saving is 12.58 billion RMB, ratio is 11%.

### 3. BENEFIT EVALUATION SYSTEM MODEL OF GOVERNMENT PROCURMENT

Figure 3.1: The structure of government procurement benefit

#### 3.1 Economic Benefit Evaluation System

##### 3.1.1 Evaluation Criteria

##### <sup>3/4</sup> Capital Total of Government Procurement

This criterion reflects the scale of procurement of a country or a district. At the same time, it is the basis of international comparison, to measure the development degree and total level of government procurement. For example, in 1998, the capital saving ratio of government procurement is 13.38%, higher than 12.96% of 2000, but the scale of the later is ten times of the former, the total capital saving increased from 4150 million RMB in 1998 to 4.25 billion RMB in 2000. This comparison shows, total capital of government procurement is

highly related to economic benefit, which is the basis of economic benefit evaluation.

##### <sup>3/4</sup> Ratio between procurement capital and GDP or Finance Expense

These two criteria reflect the importance of government procurement to national economy and finance expense. According to the experience of developed countries, the usual value of these ratios is between 10% and 30%, generally speaking, the more these ratios are closer to these numbers, the more benefit is obvious.

##### <sup>3/4</sup> The Product and Value Framework of Government Procurement

Now there are three products for government procurement in the world: goods, project and service. Generally speaking, if all the products focus on goods, this fact shows that the government procurement of this country or district is still in the primary stage, although benefit is goods, but the scale is not large enough, the levels are not enough, as the result, there would not be obvious total benefit, just like China. If the distance among three kinds of products, or the later two are larger, the fact shows that government procurement goes into the higher stage, goes deep into all the parts of economic area. At this time, the scale of total government procurement is larger, and total benefit and framework benefit becomes more obvious.

##### <sup>3/4</sup> Capital Saving Ratio

Usually this ratio for government procurement represents the difference between separate procurement expense and government procurement expense, divided with total procurement capital, but now people often use the difference between budget of government procurement and actual government procurement contracts to compute the capital saving ratio. The formula shows as following:

If  $P_{budget}$  denotes budget of government procurement,  $P_{contract}$  denotes actual government procurement contracts, then

$$\text{Capital saving ratio} = \frac{P_{budget} - P_{contract}}{P_{budget}} \times 100\%$$

Generally speaking, the more this ratio is higher, the more the benefit of procurement is more obvious. Therefore, at present the high capital saving ratio in China illustrates the fact that the budget management in China has been too loose for long time, which also reflects the necessity of government procurement system. For long term, cost saving ratio of government procurement is the scientific basis for evaluating procurement benefit.

##### <sup>3/4</sup> Development Speed

The formula is below:

If  $P(t)$  denotes the procurement capital of  $t$  year, then

$$\text{Development Speed} = \frac{P(t) - P(t-1)}{P(t-1)} \times 100\%$$

This formula reflects the dynamic development of government procurement. On one hand, high speed illuminates great progress has been achieved on the procurement work; on the other hand, it illuminates former radix is too small, the procurement is still on the primary stage and has great room and potential to develop. For example, in China, there is 3.1 billion RMB of procurement in 1998; but in the following two years, the procurement developed in the speed of 300%, the total scale of government procurement expended greatly and same things happened to the economic benefit.

### 3.1.2 Economic Benefit Evaluation System of Government Procurement

Based on the statement above, Following is economic benefit evaluation system of government procurement.

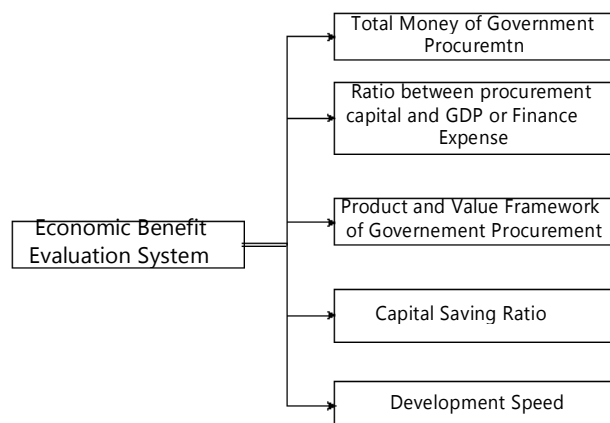

Figure 3.2 Economic Benefit Evaluation System of Government Procurement

## 3.2 Political Benefit Evaluation System

### 3.2.1 Evaluation Criteria

Political benefit of government procurement needs to be evaluated and analyzed by qualitative method. Government procurement carries on the policy mainly through accelerating social stabilization, protecting national industries to realize government benefit.

#### <sup>3/4</sup> Benefit Evaluation of accelerating social stabilization

Stabilization is the most important to politics, to maintain social stabilization is the greatest political benefit. Government procurement maintains the social stabilization through two ways: macroscopical adjustment and control; directly expand occupation.

Government procurement is an important tool to macroscopically adjust and control national economy. As the largest consumer, government owns the largest procurement scale in mass time. As a result, it would have great influence on macroeconomics operation. At the same time, government can adjust the procurement structure to adjust the industry structure, so such adjustment of economic period would benefit for stable increase of economy.

Government procurement can also increase the occupation. Occupation is a serious political problem, because it is directly related to social stabilization, related to people's basic welfare. Especially during the period of economy stagnancy, government can expand social infrastructure to increase occupation.

Based on the analysis above, we can use two ratios to measure the benefit of accelerating social stabilization: economy development ratio and the ratio of employment by social infrastructure.

#### <sup>3/4</sup> Benefit Evaluation of protecting national industries

National industries involves with national benefit, which is also a political problem. Increasing government procurement makes China more import to the world. Usually we set up related laws for government procurement to protect domestic government procurement market.

United Nation has passed some related laws and requirements to clear the trade obstacle to guarantee trade liberty, and make sure that there is no discrimination for foreign suppliers. On the other hand, under certain condition, foreign suppliers are restricted to restrict take part in the government procurement in order to protect some key departments of the country from too much international competition. Foundation and improvement of government procurement system is absolutely necessary for protecting national political benefit.

Based on the statement, we attempt to use the number of related procurement laws and requirements, and the ration between the procurement from foreign suppliers and total government procurement that reflects the international degree of government procurement.

### 3.2.2 Political Benefit Evaluation System of Government Procurement

Based on the statement above, Following is economic benefit evaluation system of government procurement.

**Figure 3.4 Political Benefit Evaluation System of Government Procurement**

### 3.3 Social Benefit Evaluation System

#### 3.3.1 Evaluation Criteria

Protecting environment, fighting against poverty, maintaining social order, belong to the benefit of public product. In order to realize these goals, government procurement needs to make some standards to evaluate its social benefit. According to welfare economic theories, increase in social benefit depends on the increase in social welfare, and increase in social welfare depends on whether personal welfare level is improved.

Although at present social benefit evaluation of government procurement is still neither complete nor correct, but from the analysis, evaluation result, we can conclude: although there are still many problems during the process of government procurement in China: just began to develop recently and the scale and scope is not large enough, the speed of development is high, the trend and progress of development is significant.

Actually, on maintaining the social order and clearing social ethos, China has achieved obvious social benefit through government procurement. Government procurement system makes enterprises realize that if one enterprise wants to win the government procurement market, it must depend on its credit and strength, it must train a sale force with high quality, which know everything about government procurement. As a result, many enterprises set up their own website to satisfy the requirements of E-government procurement, at same time make them famous and get more information of others, at the end improve the management level of their own.

Opening is the basis of justness. Justness can standardize the social order so that social benefit can be produced. The key to work out this problem is to complete and improve the present government procurement system further from the legislation.

At present, it is not obvious for government procurement to influence the social benefit from anti-poverty and environment protection, the main reason lies on the narrow scope of government procurement in China, there are still many products not included into the scope of procurement. At the same time, there are also some problems in the design of policy goals. Most government procurement focus on

economics goals, political goals and social goals still need more attention.

Based on the analysis above, we can illustrate the social benefit through two criteria: degree of justice, that is ratio between the number of the enterprises who own their own website among the suppliers and the number of the enterprises who are the suppliers of government procurement; degree of procurement public bidding, that is the ratio between procurement by public bidding and total procurement capital. These two formulas are following:

If  $N_w$  denotes the number of those enterprises who own their own websites among the suppliers;  $N_s$  denotes the number of the enterprise who are the suppliers of government procurement;  $P_{bidding}$  denotes the procurement by public bidding;  $P_{total}$  denotes the total procurement capital.

$$\text{Degree of justice} = \frac{N_w}{N_s} \times 100\% ;$$

$$\text{Degree of publicity} = \frac{P_{bidding}}{P_{total}} \times 100\% .$$

#### 3.3.2 Social Benefit Evaluation System of Government Procurement

**Figure 3.4 Social Benefit Evaluation System of Government Procurement**

### 4. MULTICRITERIA EVALUATION METHODS INTRODUCTION

The multicriteria evaluation is widely used in the social life, recent years there are many multicriteria methods emerging, mostly used are AHP (Analytic Hierarchy Process), DEA(Data Envelope Analysis), PCA (Principal Components Analysis), and Expert Analysis. From benefit evaluation system, we can see that there are many criteria to evaluate benefit of government procurement, and AHP is the most suitable method for benefit evaluation of government procurement.

In the 1970s, AHP was invented by T. L. Satty, who was an American expert of operational research. AHP has been used to system analysis and strategy research in the area of economy and politics, with the characteristic of practicability, terseness and validity. The process of AHP includes problem conceptualization, hierarchy structure foundation, consistency judgment matrix formation and so on, consistency judgment matrix formation is one of the key steps. This method can be used to research more complex multicriteria decision

problems, quantify the qualitative factors, to some extend test and reduce the subjective influence, and make the evaluation more scientific. In 1982, Mr. Xu shubai introduced it into China.

When the entire benefit of government procurement is evaluated by using AHP, first step is to separately, evaluate economic benefit, political benefit and social benefit, then get the values of each benefit; second step is to give weight to each benefit according the opinion of the decision maker, at last add up these weighted values, then get the final evaluation value. Decision makers can compare evaluation values of some years to give some advices for developing and improving government procurement work.

5. INFORMATION COLLECTING OF GOVERNMENT PROCUREMENT

From the analysis above, some information needs to be collected to convenience the benefit evaluation of government procurement. Such information can be divided into two types: statistic information, statement information. For statistic information, there is horizontal information, longitudinal information, annual statistic and so on, in the form of digital information. On the other hand, statement information is mainly the information that describes the characteristic of government procurement behavior, in the form of letters. Based on the former analysis, we get the a brief summarization of information collecting of government procurement:

Table 5-1 Information Collecting	
Statistic information	Statement information
Monthly procurement	Type of procurement product
Annual procurement	Import or export
Finance expense	Degree of justness
Budget of procurement	Degree of publicity
Actual contracts sum	----
Laws of procurement	
District procurement	
----	

During the process of government procurement, the information mentioned above should be paid more attention in order to evaluate the benefit of government procurement efficiently, effectively, conveniently.

6. CONCLUSION AND FUTURE RESEARCH WORK

As an important part of E-Government, E-Government Procurement has a great influence on the development of economy. Government procurement is one key node in the public finance system, which is one of the basic methods to perform the national finance management and payment in the system of market economy. Because

the characteristic of Government procurement is “justness, justice, open”, it can greatly prevent the malversation, such as some personal operation and corruption, as a result usually the government procurement can be called as “project in the sun”. Normative government procurement has the important meaning to the incorruption in the government. How to realize E-government, and how to use present information technology to evaluate the whole benefit of government procurement, that is the present focus of government affairs.

As the situation of global government procurement shows, E-government procurement is inevitable, which is the direction of government procurement reformation. In term of the general rules of E-government procurement, together with the fact in China, the basic design of E-government procurement is: strengthen the research and programming of E-government procurement, establish the mutual mechanism of government procurement reformation with E-government procurement step by step.

In China, the benefit evaluation of government procurement is still on the primary stage and still in the process for groping. In fact, most present evaluations are focus on the economic criteria, not social criteria and political criteria, and ordinarily strained to a few special criteria for quantity analysis. On the other hand, the result of evaluation is often affected by the value judgment, knowledge, experience of person who is making the evaluation, as well as by the quantity of the material and the relationship between the person making evaluation and the object evaluated, what is mentioned above will finally influence the justness and objectivity of the evaluation results.

This paper attempted to set up the evaluation system of the whole benefit for government procurement, separately from economic benefit, social benefit and political benefit three parts to explain the source of government procurement benefit. According to the different type of benefit criteria, different quantity and qualitative methods are used to evaluate the benefit: concretely speaking, for economic benefit, measure criteria are used; for social benefit and political benefit qualitative criteria are used.

The future research work will focus on exploration of the evaluation method for the enterprise procurement in or out of China, and those of government procurement in developed countries, some reasonable advice from the above will be provided for building a China-fitted evaluation criteria system according to China’s situation. Scientific, reasonable, standardized benefit evaluation system for government procurement can make the evaluation process more easily, operation more conveniently, the time for evaluation less, at the same time, the lessons and experience of procurement can be summarized in time, as a result government

procurement becomes more transparent and more “sunlight”.

### ABSTRACT

E-business development is a considerable complicated task because the underlying logics of e-business and its new processes that are originated from implementing enhanced information technologies to streamline business performance introduce many complex issues. One of the difficulties is to capture the dynamic aspects of e-business that can be used for monitoring the business performance, in a way that could be helpful for the business adaptation to meet competitive advantages. Among many dynamics of e-business, the value system is the most interested one that has recently been addressed. However a value system is at the strategic level with no formal approaches for its representation, which introduces a gap between system modelling and implementation in the e-business development. In this paper, we will investigate a so called value process that can be not only used for value system modeling, but executed for simulation of the resulted model. For the purpose of value process modelling, we will adopt the process algebra approach, which will be integrated with others such as workflow in our modelling environment.

**Keywords:** E-business, value system, value processes, e-business modelling.

### 1. INTRODUCTION

There are considerable difficulties in modelling e-business and its processes, because e-business dramatically changes traditional business value systems and the patterns of action and interaction that bring together processes from different companies, sites, suppliers, distributors, service providers etc, as well as the new processes emerging from business needs to support the collaboration, coordination and cooperation. The e-business era has introduced many new paradigms, that has given a rise to a need for appropriate tools and modelling mechanisms that support for the better understanding and the decision making of the business and its process development.

An e-business is considered here as the integration of business rules, a viable trading mechanism and associated processes into a business approach that leverages the network (Internet) as its medium of transaction, it is thus composed of the characteristics of the definition of the offered products and services, the targeted customers, identification of the involved business partners and their roles, and the value propositions among business actors. With this context of e-business, the business strategy analysis will be, not only in business itself but in business process as well, an important element in e-business development. The business strategy analysis is a methodology of configuring the business value system that consists the value architecture and the value dynamic at run time. For the given business strategic plans and goals, the processes of developing a sound value system and value process underlying the value system become vital for e-business to be successful.

Recently the value based approaches have been advocated in e-business modelling [1, 4, 6, 8, 17, 23]. In these modelling proposals, e-business modelling is about the value and value operation for what is offered by who to whom in term of value, while e-business process modelling is the concerns of how the value offerings are selected, negotiated, contracted and fulfilled operationally [3, 4, 7, 21]. In [5, 6], an  $e^3$  value based approach has been proposed that rigorously describes value exchange among business actors and formalises a value exchanging architecture based on requirements engineering and case mapping techniques. Because of the "soft" and complex nature of e-business, the description of e-business modelling is remained at the conceptual level, some graphical tools have been developed for visualising the business actors, value flows and value relationship among the actors, which can help in e-business value system development [4, 5]. However, the lack of computation mechanisms in the conceptual model of the value system causes the difficulty for simulation and feasibility testing. In this paper, motivated by e-business modelling demands, we propose a novel value process modelling approach that brings the e-business modelling and its process modelling together in a single form. With the computable for simulation in our mind, we adopt the process algebra [2, 11] as our modelling language that addresses two fold in e-business modelling - static and dynamic characteristics of the e-business value system. The value process of e-business is nothing but the values and operators that model what and how the value is created and transmitted within e-business with respect to the strategic plans and goals.

This paper is to study the value process modelling, and examines how to facilitate the modelling results to

derive e-business processes. The remainder of this paper is organised as follows. Section 2 presents the background of e-business modelling by reviewing the requirements in e-business modelling demands, and addressing the important relationship between the value system and the e-business process. In section 3, the value process is discussed using the adopted process algebra. In section 4, we give an example to show how the value process can be used in e-business modelling and development. Finally in section 5, the conclusion is given, and our further considerations for the remaining issues are addressed.

## 2. BACKGROUND

In this section, we briefly review the related literature in e-business modelling from the value point of view, and examine the value system of e-business, which gives the background for our development of the value process.

### 2.1 Value Based e-Business Modelling

An economic activity is directly toward the creation of value. A business is considered superior comparing to others, if that business offers a superior value to its customers in the competitive marketplace, and gains benefits from it. A value is an economic concept, not primarily measured in physical performance attributes, rather what a buyer will pay for value object - product, service, information and knowledge. A description of these related strategic value plans is *Value Proposition*. The constituents of a value proposition may include the clear answers of questions such as

- What are the contents of value to be offered?
- Who are the end users of the value?
- Where are the end users?
- What are the benefits for the end users, partners and itself?
- Why ought the end users accept the value offered?
- What the benefits the business can gain by offering the value?

Value proposition can be understood as the statement of benefits that are delivered by the business to its external constituencies, and that are gained to the business itself. However, the statement of a value proposition is often an informal one that can only be understood by the experienced business modellers. It is difficult to be understood by those who carry the development of the e-business processes and softwares. It is preferable that a formal approach defines a value proposition. Inspired by the works of several researchers in business modelling [4, 10, 12, 21], the value proposition may be described by four attributes including customer needs, value creation, value level and value price level. These attributes are closely related to the value articulation. The customer needs include the concerns of usefulness, risks and effeteness of the value offered to the

customers. The value creation is the way of how the value can be created at the moment of the value life cycle of value object creation, consumption, renewal and transfer. The value level is the measurement of the value comparing to its competitors in scales of similarity, innovative imitation, excellence and innovation. And the value price level is the proposed price by comparing to one or all of the competition in the scale of free, economy, market and high-end. We note that defining a value proposition is the first step in e-business development, which requires business strategies that clearly point out the attributes of the value proposition. A value proposition, however, only provides a broad view about what the values of the business are to customers and itself. We can not see how the business operates the values at this level of modelling phase, which a value architecture is required that describes the partners' value relationship, capability, competence and resources for fulfilling the value propositions.

The value architecture addresses the problems such like who are involved and what the roles the actors play in the business, what relationships are among actors, and what activities and resources are needed to fulfill the promised benefits to the customer in an efficient way. The value architecture has been explored by several researchers, for example the  $e^3$  provided a model of the value architecture that focuses on value and value exchange [5]. Generally speaking, the value architecture can be regarded as a value system that is a connected series of organisations, resources, and knowledge streams involved in the creation and delivery of value to the end customer. It is centralised about the value creation process and the problems of how to anticipate customers' and partners' processes by using Internet technology. Value systems integrate the business activities, from determination of customer needs through product/service development, production/operations and distribution. For such integration, it is required that the processes underlying the value system have to be explored. We consider that the value system is the aggregation of value processes that need to be modeled for e-business development.

### 2.2 Value System and E-Business Processes

To approach each business opportunity, adaptive business processes are required for continuously restructuring value systems. The relationship between the value systems and e-business processes is that the former provides the guidelines for how the e-business process should be in order to offer better values to its customers, while the business processes support the value systems such that the valid processes are facilitated to fulfill specified requirements of the value systems. Figure 1 shows the relation between them in the e-business development life cycle. However in addition to the conceptual level of the value systems in which might be difficult to be executed for simulation, the current approaches separate these issues that

introduce the gap that gives a rise to the transitional difficulty from a value system to a process system and vice versa. We need a modelling mechanism that supports the understanding of e-business and system development. We found that the difficulty is laid by the representation of the value systems, in which the dynamic aspects of the value systems can not be captured. Since a business process is an operational system that directs the business activities in steps, the conceptual model of the value systems might not be able to reveal the insights of the dynamics in business processes. A different notion is required for value system that bridges the gap of the value system and the e-business process. The value process, discussed in the following, is proposed to this challenge for e-business modelling, and it provides the syntax and semantics of a value system to capture the dynamic nature of the e-business systems.

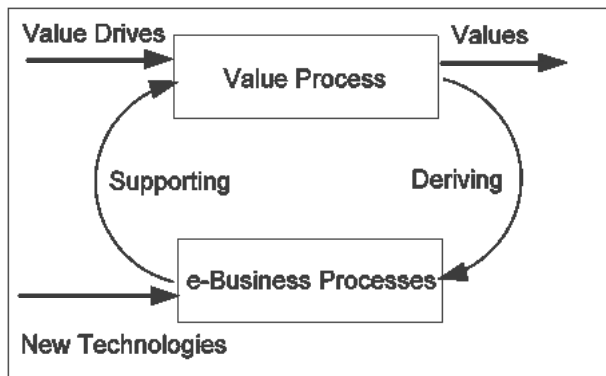

Figure 1: The dynamic relation between value process and business process.

### 3. PROCESS MODEL OF VALUE SYSTEM

Most of e-business modelling methods are text or graphic based that can explain the value system but provides the drawbacks in depicting the dynamics. Our modelling approach takes from the process point of view that provides the semantics of the value system in the sense of the formalisation of the value system that the modelling result can be executed for simulation. In dealing with the value process, our modelling notion adopts the process algebra for business applications such like concurrency and synchronous/asynchronous with respect to value. At the high level of value process, the primitives are agents and the interaction among them. On another hand, at the low level of value process (business process), the primitives are processes with the actions and activities in value creation.

#### 3.1 Value Process Description

Two types of actions are 'input' and 'output' for a given 'value channel'. Let  $x, y, z \in V$  be a set of value objects, and  $a, b, g \in C$  be a set of value channels. The prefix actions for a process are as

$a(x)$  : The action of inputting the value  $x$  along the value channel  $a$ .

$\overline{a}(x)$  : The action of outputting the value  $x$  along the value channel  $a$ .

We denote the prefix action set,  $A_v$ , which means that each action in the set is either input or output with the specified values and channels. Value process primitive  $P$  is an activity that acts on the value via the channel, and has its continuation of the process, denoted as  $v.P$ . In addition to the value process primitive, a set of operators expresses the composing rule of the primitives that form a complex process. Let  $P, Q \in \mathbf{P}$  a process set, symbolically, the syntax rule of a value process is defined as

$$P ::= v.P \mid Nil \mid P + Q \mid P \mid Q \mid (rx)P.$$

where  $v \in A_v$ , a prefix action of input or output. The semantics of the value process syntax are intuitively understood as follows:

- Process  $v.P$  defines a process with the value action prefix and continuation.
- Process  $Nil$  defines a value process that is no longer active to its environment.
- Summation process  $P + Q$  represents an alternative of two independent processes that can be selected. Either  $P$  or  $Q$  is performed by the process at a time, but not both. For instance, getting the information of a value object either by searching on the Internet or reading from a newspaper.
- Composition process  $P \mid Q$  represents two independent processes that are value dependent or independent parallel processes. When dependent, the process is interacting via its channel  $a$  and value  $x$  such as  $\underline{a}(x).P \mid \overline{a}(x)Q$ , meaning that  $P$  and  $Q$  are dependent processes with respect to value prefix  $a$ ,  $P$  acts offering value  $x$ , and process  $Q$  performs a complementary action receiving a value for the value process.
- Restrict process  $(rx)P$  means the value process restricts its process on value  $x$ .

The notation of the value process above gives the process with the value and the channel as activity parameter. It is easily extended into multi-parameters expressed as  $(v_1, v_2 \dots).P$ , where  $v_1, v_2 \dots \in A_v$ , the syntax rule for a value process remains unchanged. The description of dynamic aspects of the value process is achieved by defining the deduction rules that govern the process at run time. Just as in the traditional process algebra, there is only one deduction operator  $\rightarrow$  over process;  $P \rightarrow P'$  means that  $P$  can be transformed or evolved into  $P'$  by a single computational step. In

general, the interaction between two value processes is defined according to the following inference rules:

Interaction :  $\bar{a}(x).P \mid a(y).Q \rightarrow P \mid Q\{x/y\}$ .

Parallel :  $P \rightarrow P' \Rightarrow P \mid Q \rightarrow P' \mid Q$ .

Restriction :  $P \rightarrow P' \Rightarrow (rx)P \rightarrow (rx)P'$ .

Structure :  $Q = P, P \rightarrow P', P = Q' \Rightarrow Q \rightarrow Q'$

The process algebra has its richness of mathematics. However we are interested in the use of the notion for value system modelling. By adopting it for the process of the value, we arrive at the value process, which we will intend to use for value system modelling.

### 3.1 Value Process Modelling

Based on the value process, we discuss how the notion can be used for value system and business process modeling. In e-business modeling, the value proposition is the first step getting into understanding the logics of e-business. We assume that the value proposition is articulated for use, and the information about values, actors involved, the competences and resources required of e-business are available. To represent a value system that connects these resources together, the value process is used to describe the actors and roles, and the value relationship among the actors.

A value process agent,  $A$ , is a value process that offers or receives the value and continues the process. We note that an agent may be a primitive value process,  $A(v) = v.P$  or a composed one. In general, the agent may take many parameters as its prefix actions as required,  $A(v_1, v_2, \dots)$ , while the value relationships are described by how the value is offered and received among these agents, and what value process are required for each agent to fulfill the value relationship.

We use the value process agent to represent the business actor. The parameters that agent takes are considered as tasks that agent will perform. An agent is an independent entity. The connection of agents is done by matching the dependency of the tasks dedicated to the agents. For example, assuming that there was three agents denoted as  $A_1, A_2, A_3, \dots$ , each agent performs the tasks such as  $A_1(v_1, v_2, v_3), A_2(v_2, v_3), A_3(v_1, v_2)$ , where  $v_1, v_2, v_3$  is the task set. Then

$$\text{System} = A_1(v_1, v_2, v_3) \mid A_2(v_1, v_2) \mid A_3(v_2, v_3)$$

It is an abstraction of the value process system, which only states the agents and their roles in terms of tasks. Elaborating this abstraction, we can examine how agents interact by expending the value process into the details with respect to tasks that an agent performs.

For example, we can specify the channels between the agents in term of the tasks.

$$A_1 \mid A_2 \mid A_3 \rightarrow \bar{a}(x)P_1 \mid a(y)P_2 \rightarrow P_1 \mid P_2 \{x/y\}$$

Here we assume that  $\bar{a}(x)P_1 \in \mathbf{P}_1$  and  $a(y)P_2 \in \mathbf{P}_2$  are two process sets that agents  $A_1$  and  $A_2$  will carry out to fulfill their tasks. The transformation of steps indicates the processes required for the value transmission between agents. Actually, we see that the detailed value processes can be regarded as the business processes, which show how the value is processed, created and added in each process step. We do not go further for the business process here as the purpose of the value process is to model the value system. The process notion discussed in the previous section provides enough information that supports the business process development, which will be our further interests in e-business modelling.

The financial structure of the value systems is one of the important modelling issues. For a given value system, we can inspect the financial aspects of the value process by estimating the cost and revenue sources, aggregating for the overall of the agent financial performance. We do these within the value process by defining a set of value calculators that estimate the cost of each process at the modelling phase, and compute the running cost and the revenue at the simulation phase in order to estimate the profit for each agent.

$$\text{Benefit} = \text{Revenue} - \text{Cost}$$

We argue that the financial aspect of e-business model can not be measured statically. The revenue sources and costs of the value system are dependent on running the system in which the transaction is made. The value process has detailed each value transaction between agents, thus it is possible to estimating the financial aspect of the value system at the simulation phase.

To this end, we believe that business knowledge and skills in strategic analysis are the critical and the most important component for the issues such as value capturing, activity identification, partner selection and pricing in designing an e-business system [10,13]. These issues are separated from the value process since the focus of value process modelling is to exploit the ways of how the value is processed in terms of creating, adding and distributing value and revenue among business actors. Developing a value system for business innovation or a new business idea is to capture the values to the customer and customer's values, which is a very sophisticated business process. We do not concern the value capturing; rather assume that there is the related information about the values that have been identified and available for the value process. To summarise the value process modelling, the following steps are considered:

- Articulating the values for a new or innovated business idea.
- Constructing value proposition of e-business.
- Investigating the value relationships between stakeholders, partners and customers.
- Constructing the value process system for a given value proposition.
- Estimating the financial aspects of the value system.
- Revisiting the value system for value refinement if necessary;
- Developing the business process to support the value process system.

## 5. AN EXAMPLE

We look at an e-business “brokerage model”[15], and examine the value process in the model. Then we inspect how the value is processed in the model. The brokerage model has ten sub-models including Marketplace exchange, Buy/Sell fulfillment, Demand collection systems, Auction broker, Transaction broker, Bounty broker, Distributor, Search agent, and Virtual Mall. Three process agents involved in the model, namely Seller, Buyer and Broker. The “flow-graphic” of the auction broker sub-model is shown in Figure 2.

Figure 2: An auction model of e-business

In this auction model, the “Broker” provides the Internet services that a “Buyer” or “Seller” can use for the information of the goods and buying and selling the goods. On the high level of the business description, the Broker does the activities of auction by taking the information of goods from the Seller who wants to sell and auction the goods on behalf of the Seller, it charges the Seller a listing fee and commission scaled with the value of the transaction. On other hand, the Broker interacts with the Buyer according to offering and bidding rules, and finally fulfills the goods including price, delivery, etc. Three value process agents, involved in this model, are Broker, Seller and Buyer. A value set that describes the value relationship among the process agents are goods, money, service and information. Here we do not model the channels that are assumed as the Internet, and we only show the value system of auction and the business processes that the agents must perform.

The auction model is defined as

$$\text{System}_{\text{Auction}} \stackrel{\text{def}}{=} \text{Buyer} \mid \text{Broker} \mid \text{Seller}$$

The tasks that each agent will perform are

$$\text{Broker} = \text{Broker}(s1, s2, lf, af),$$

$$\text{Buyer} = \text{Buyer}(s1, g, gp),$$

$$\text{Seller} = \text{Seller}(s2, lf, g, gp),$$

where  $s1$  and  $s2$  present Broker’s offered services to Buyer and Seller respectively, and  $lf, af, g, gp$  means the listing fee, auction fee, goods, goods payment respectively.

In the auction model defined above, the system shows that the agents and the value relationship between them. Next we define the processes for each process agent:

$$\text{Broker}(s1, s2, lf, af) = \overline{s1}.B_1 + \overline{s2}.B_2 + \underline{lf}.B_3 + \underline{af}.B_4$$

$$\text{Buyer}(s1, g, gp) = \underline{s1}.C_1 + \underline{g}.C_2 + \overline{gp}.C_3$$

$$\text{Seller}(s2, lf, g, gp) = \underline{s2}.D_1 + \underline{lf}.D_2 + \overline{g}.D_3 + \underline{gp}.D_4$$

where  $B_i, i=1,2,3,4$ , is Broker’s process,  $C_j, j=1,2,3$  and  $D_k, k=1,2,3,4$  are the processes of the Buyer and Seller with the prefix actions specified. If an interaction occurs, for instance between Broker and Buyer, at a service step, then the system is evolved into

$$\text{Buyer} \mid \text{Broker} \mid \text{Seller} \rightarrow \overline{s1}(x).B_1 \mid \underline{s1}(y).C_1,$$

which indicates that the Broker and Buyer are interacting via the service channel. For the negotiation processes between the Buyer and Seller and negotiation service provided by the Broker, we can go further to detail the processes implementation. However, it is unnecessary to give the trivial list of the processes.

The example of e-business modelled here by the value process shows three aspects. The value process gives the elements for the representation of the concepts of the value system, it glues the value system and business process together and the changes in the value system can be easily modelled to adjust the underlying process. The model can be simulated for reducing the risk of business development. For a particular e-business case, the value process should be made in a unique way for the competitive advantage. A value process aims at what and how the value is created for the targeted customers. The main benefit of a value process, from the competitive advantage point of view, is that it can be simulated, tested and reconfigured to meet the business strategic goals. For an identified value, how the value is processed among the business actors is determined by value-added analysis - an engineering pattern that focuses on eliminating activities that do not add value,

which has not modelled, but will be considered as our further investigation.

## 6. CONCLUSION AND FURTHER WORK

In this paper, we have proposed a novel e-business modeling approach. The core of the approach is a value process. The modelling approach is different to others: First it is a value driven approach concerning the values to the customer, then a value process focuses on what activities are required and how the values are created, finally the value system is configured through agents sharing the activities in the value process. We have pointed out that the business strategy is one of the most important components in constructing an e-business system. The business strategy analysis must be carried out on each phase of business modeling to build a competitive business system. An example of Brokerage model is given to demonstrate the modeling approach. Our further work will be to develop a modeling environment to support the modeling methods.

## ACKNOWLEDGEMENT

Work reported in this paper is partly supported by Swinburne Vice Chancellor's Strategic Research Initiative Grant 2002-2004 for project "Internet-based e-business ventures".

## Evolution of Service Model and Architecture of ASP Business

Kangrae Cho, Hojoon Choi

Service Development Laboratory, KT, 17, Woomyeon-dong, Seocho-gu, Seoul, 137-792, Korea  
{broncho,chopchop}@kt.co.kr

### ABSTRACT

ASP has been a buzzword among enterprise IT area since mid 1990s. Following after the hype cycle of new technologies like others, many market analysts say that ASP technology is now in a plateau of productivity sequence through trough of disillusionment sequence over past 5 years. In the Republic of Korea, MIC (Ministry of Information and Communication) and KT began ASP service called bizmeka<sup>®</sup> to help companies adopt the newest information technologies on KT's information superhighway since 2000. Like other ASP players in other countries, there were similar obstacles and problems that are difficult to solve. But with the introduction of new concept of service model and architecture, the difficulties of managing business improved. In this paper, we will discuss about how ASP business of Korea started, managed and made evolution of service model and architecture to meet the various demands of enterprises over past 4 years.

**Keywords:** ASP, Outsourcing, Enterprise Computing, Web Services

### 1. OVERVIEW

Today's companies are depending heavily on the newest enterprise software, cutting edge hardware and broadband network to correspond with the rapidly changing market environment. Information technologies that are selected in contemporary corporations give much benefit to them. On the wile, it requires much enterprise resources such as software, hardware and network and operation staff for being beneficial to them. In this point of view, renting an enterprise information technology is much more profitable rather than possessing the whole software, hardware and operation staff considering today's company's situation that must utilize effectively its manpower and money.

Especially in SME (Small Medium Enterprise)'s viewpoint, the needs of renting an enterprise information technology is much bigger than that of a large enterprise. In enterprise information technology market, ASP (Application Service Provider) based service which is capable of constructing enterprise information system rapidly and economically attracted attention of companies from mid 1990's along the boom of the internet. With the advent of ASP business model, ASP sector also won many IT vendors and IT market analysts to its side [2].

Meanwhile, Korea had a different situation compared to other countries with the rapid growth of Internet subscriber over xDSL and cable modem. Most government and public offices and companies have been able to connect to the Internet with low-priced subscription fee and people have come to bear in mind the digital economy and culture gradually. Particularly, to strengthen the domestic and international competitive power of SME in Korea, MIC and KT began an ASP support program. Under the policy of KT's new business model excavation promotion, bizmeka has been successful in ASP area with the growing revenue and

increasing subscriber since 2000, satisfying customer's needs through evolution of service model and architecture of ASP service platform.

### 2. MARKET TREND & FORECAST

ASP industry received the spotlight by its rational business model with the Internet boom and Dot-com bubble from 1997 to 2000 by the press. But recently, the descent of IT economy and the collapse of Dot-com bubble burst resulted in merge and acquisition between ASP players and retirement of incompetent ASP players. On the while, the expectancy of ASP market settlement is growing bigger with the overcoming of the hype and immaturity of the new technology and ASP market.

Fig 1. ASP Hype Cycle by Gartner Group

As Figure 1 shows, Gartner expects that ASP technology will be in a plateau of productivity sequence through trough of disillusionment sequence by 2004 following after the hype cycle model of emerging technologies. IDC also expects that the number of ASP player will drop to 389 on the year 2005 from 800 on the year 2000 with the yearly decreasing rate of 13% by severe competition between ASP players, excessive initial investment cost, uncertain business plan and difficulties

in financing. [7]

IT market analysis firms like IDC, Gartner, Ovum are issuing research reports which are being optimistic about current and future ASP market. IDC predicts that the global ASP market size will be 19.9 billion dollars until 2006. Dividing ASP market by region, as Table 1 shows, U.S will occupy 58% of the whole market by 2006 with the market size of about 11 billion dollars and EU market size will be reached to 6.7 billion dollars by 2006 growing from 306 million dollars on 2001. In that, Asia-Pacific ASP market will be 1.5 billion dollars size, but we may expect more big figures in this area considering recent brilliant economic growth of China even considering IDC's forecast. [8].

Table 1. ASP market forecast by region  
(Unit: Million US\$)

	2001	2002	2003	2004	2005	2006
U.S.	1,329	2,173	3,494	5,495	8,105	11,667
EU	306	749	1,622	3,036	5,122	6,726
Asia	156	280	441	694	1,071	1,572
Sum	1,791	3,202	5,567	9,225	14,928	19,965

## 2.1 United States

ASP market in United States showed emergence in 1998 by the companies like Corio and USInternetworking and came into expansion stage during 1999~2000 with many participating ISVs. But the market expansion stage soon stepped into declining stage along with collapse of Dot-com and burst of IT bubble. But from the year 2001, ASP market entered into new era with the M&A between ASP companies and new participant from IT related companies.

There is also continual specialization and subdivision in ASP market after Dot-com crisis. At first, most ASP player thought that price-sensitive SME is their best potential customer for their services. However, there are increasing cases of contract of providing ASP services to a certain company's department partly not to the whole departments. For example, Salesforce provides their Sales Force Automation solutions only to marketing and sales department of America Online, Mitsubishi and Fujitsu

Even new trends and diverse approach method to market, ASP customers in United States are still worrying about problems that are hard to solve like security concern when depositing their valuable data to distant location other than their office and integration problem between ASP application and legacy application and so on. so ASP players are striving to solve these problems by adopting new emerging technologies like EAI (Enterprise Application Integration) or Web Services.

Nowadays, there is an apparent tendency of big IT company's entrance into ASP market. Microsoft has recently announced publication of low-priced CRM software package and participated in ASP business. SAP

and Peoplesoft also have plans to strengthen marketing in SME sector and Oracle has launched new organization for managing new ASP business which rents their solutions on the internet escaping from direct sales over CD. IBM also announced that they are building datacenter infra to prepare for ASP business by packaging their software and solutions into ASP-ready products. [8]

## 2.2 Japan

In the year 1999 and 2000, ASP business was considered as a good business model with great anticipation. In Japan, but after burst of IT bubble and the collapse of Dot-com companies, Japanese ASP industry also gone into recession period until 2002. But with the explosive growth on broadband internet connection service, ASP industry has been paid attention to again with possibility.

The Japanese ASP market stated with HR, finance, tax management software on the while ASP market in U.S. are ignited by cheap rent of expensive ERP solution. Especially in Japan, ASP gets its attention in public and government sector. Japanese government now drive sharable outsourcing IT infra project by the initiative of 3,300 local provinces. [8]

## 2.3 EU

IDC predicts that European ASP market will grow 85.6% during 2001~2006 and market size will be 67 billion dollars until 2006. The initial ASP players in European market almost come from United States. Most of the m failed to successfully enter into emerging ASP market. But they are preparing to reenter into new market by new solution, services and technologies.

Most distinguishing project related to European ASP market is "ALTERNATIVE" which driven in public and government sector. The objective of "ALTERNATIVE" project is eventually to strengthen competitive power of SME by allowing selectively choosing their needed solution. [8]

## 2.4 Summary

We can discover some interesting points by reviewing ASP market trends, status and activities in United States, Japan, and Europe.

Firstly, even big and famous ASP players focus their strength on revenue and profit rather than technological advances by world wide IT economy recession.

Secondly, to win over deepening competition between ASP players, they are trying to seek their own distinguishing services and solutions for customers to discriminate them from other ASP players.

Lastly, multinational companies like Microsoft, IBM,

SAP and Oracle are preparing to enter into ASP market. so existing ASP players are now on the strain for the upcoming competition with well-known package solution vendors.

### 3. ASP BUSINESS IN KOREA

The Republic Of Korea drives internet boom which is begun from late 1990s and now 30 million users are using the internet and 11 million houses are connected to the internet via xDSL, Cable-Modem or Optic Fibrer at the speed of ranging from 2mbps to 100mbps. In addition, most Korean companies utilize corporate homepages for advertisement and customer contact point.

But comparing the rate of IT infra utilization, the utilization rate of households and large corporations are already reached that of advanced countries. On the while, The IT utilization rate of 3 million SMEs which comprises 99% of Korean companies is apparently low because of its high initial construction cost and management cost. So The Government of the Republic of Korea and KT are doing ASP business called bizmeka for SMEs to inspire the IT mind and spreading of the new enterprise information technology based on KT's broadband internet infra and domestic enterprise solution for SMEs from 2001[3].

On the while, the Korean ASP market size is about 100 million dollars in 2002 and will grow 53% annually until 2007. This growth rate is somewhat dependent on Korean economic recovery on domestic sector. Since most solution provided in ASP industry is mainly focused on domestic business not on global business like export and import goods.

It is shown by survey research that over 71% of SMEs in Korea prefers IT system construction by outsourcing, purchasing and ASP not by operating their own staff and develop their own solution. Especially 44% of SMEs chose the outsourcing as the best preferable method of constructing their own IT infra. It can be easily estimated considering SME's weak IT solution development capability and small IT management budget. We can also expect that SME's dependency and preference over ASP and outsourcing model will be heavier as time passes.

#### 3.1 solutions and services of bizmeka

Starting from web based corporate email and groupware services, bizmeka provides currently about 70 kinds of services ranging from general business solutions from a groupware to core enterprise solutions like ERP, SCM and even special sector solution like IP camera surveillance for 51 thousands companies and 110 thousands employees and employers.

Intra-Enterprise solution sector includes ERP, Production SCM, Groupware, Tax and Finance Management, Sales

and Stock Management, Mobile SFA, IT Equipment Rent and IT consulting service. Collaboration solution sector includes Merchandising SCM, Electronic Tax Receipt and Social and Medial Insurance EDI (Electronic Document Interchange). On-Line solution sector includes CRM, internet shopping mall builder and homepage hosting. Vertical industry solution includes Auto shop management, Optician's Store management and Catering Management.

#### 3.2 architecture of bizmeka service platform

It is very difficult and complicated work to ensure integration between diverse solutions and manage multiple modern enterprises' information system without hassle. To support it stably, perfect and reliable AAA (Authentication, Authorization, Accounting), billing, order management, customer management is key issue of running that kind of system. KT has been running bizmeka platform to run above functions since November, 2002 after one year's research and development

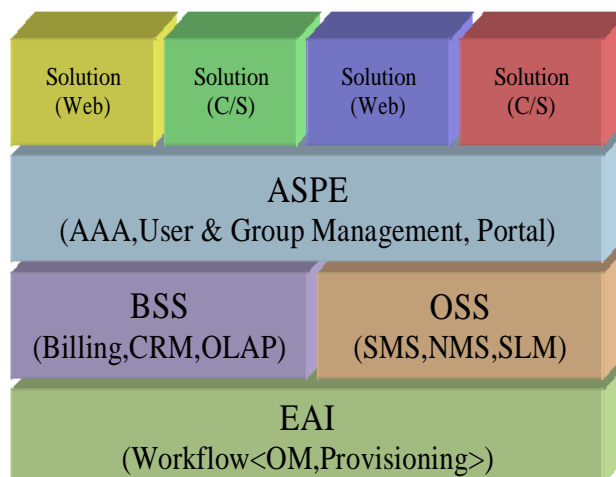

Fig 2. Initial architecture of bizmeka

As Figure 2 shows, ASPE (ASP Enabling) is subsystem that supports AAA of ASP users, organization management and SSO (Single Sign On) over portal. All of them is necessary for using ASP solutions easily and securely. ASPE also has Mobile SMS (Short Message Service), User Community and BBS (Bulletin Board System) which can be used as building blocks of other solutions.

BSS (Business Support System) includes billing management which is crucial for running charged service, ASP user management and OLAP system which gathers and analyze sales related information. Billing system sends a bill to user by sending bill information to existing KT's PSTN (Public Switched Telephone Network) billing system.

OSS (Operation Support System) includes IT resource (Network, Server, Storage, Software) management system to effectively manage massive IT systems. It also

includes SLM (Service Level Management) subsystem which detects failure of services and measures service quality over the network since there are many services and solution based on internet.

EAI system provides reliable message transfer service between servers and message transformation service with orchestration of workflow service. Whole messages are expressed by XML and even heterogeneous systems based on Java or .NET can send and receive messages to each other freely. It also supports reliable, long-running transaction based workflow process like provisioning new services and registering new ASP user after verifying one's credit status.

#### 4. EVOLUTION OF SERVICE MODEL AND ARCHITECTURE

Though bizmeka started with web based solutions on early stage, there was no choice but to accommodate the various demands of companies to meet the customer needs and extend business area. So now bizmeka have general service architecture like EIP (Enterprise Information Portal) and unique and rare kinds of service architecture like VIP (Vertical Industry Portal), MSP (Mobile Service Platform) and APP (Application Publisher Platform). bizmeka also has special kinds of service model such as Remote Hosting and AIP (Application Infrastructure Provider).

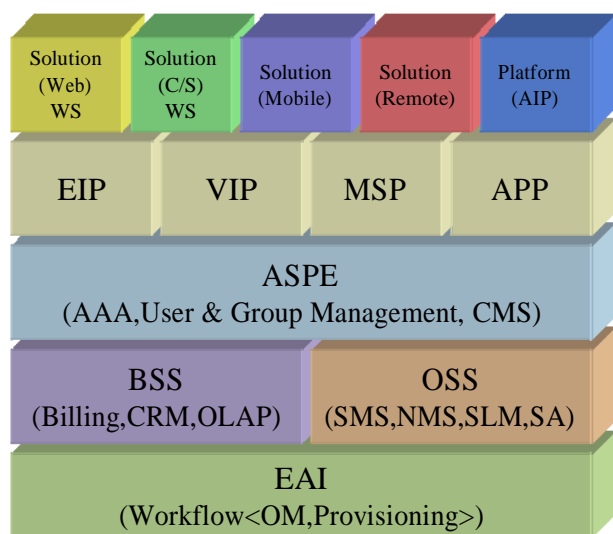

Fig 3. Current architecture of bizmeka

##### 4.1 Portal service platform

EIP is an portal service platform which integrates applications (email, contact list management, bank account management ...) together and provides SSO (Single Sign On), privilege management and personalization to give user the simple way of using the solutions and control authentication and authorization of users on one point. EIP platform includes Multiple Enterprise Support, Site Template Engine, Caching Engine, Content Management Engine, Personalization

Engine, AAA Manager and Service Monitor. With the help of EIP platform, users can aggregate many solutions easily after one successful authentication.

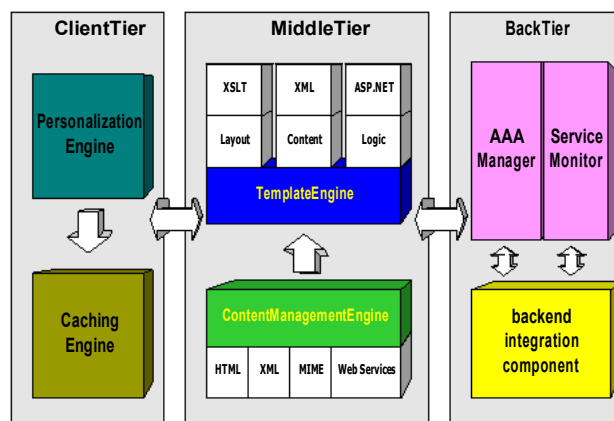

Fig 4. Portal architecture of bizmeka

VIP is designed to help building the vertical industry portal site easily and rapidly. The purpose of EIP is an solution integration but VIP's purpose is to allow building the vertical industry portal in short time using the site template and site management functions in the VIP platform. VIP shares the same portal infrastructure with EIP as shown in Fig. 4. But VIP platform has additional components like site build wizard, handy and easy site management interface and many web interface decorating functions.

##### 4.2 Mobile service platform

MSP is recently added to meet the growing needs of mobile applications and devices like mobile phone, smart phone, PDA and industry specific embedded mobile devices. This platform includes mobile security support system including mobile PKI and data encryption and decryption, contents conversion system supporting HTML, WML, cHTML, WAP and application & data sync system. With the wide acceptance of mobile technologies and devices, the usage of MSP is expected to grow as time goes on.

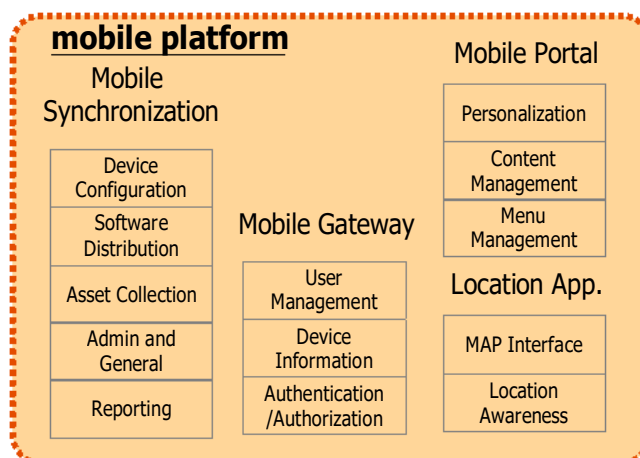

Fig 5. Mobile service platform of bizmeka

### 4.3 Application publisher platform

APP is a service platform that provides whole or part of platform services through web services to ease the migration of ISV (Independent Solution Vendor)'s solution which already have their customers. In this case, it is really hard to integrate user information and user interface seamlessly to bizmeka. So Application Publisher helps ISVs integrate their solutions to the bizmeka platform loosely and transparently to their existing user.

Fig 6. Application publisher Platform of bizmeka

### 4.4 New kinds of service model

Remote Hosting is a kind of remote management service model for solutions like ERP and SCM which is deployed on customer's site. Operation staff of bizmeka always manage and monitoring the remote applications, servers 24/7. Nowadays the concept of Remote Hosting is extending to the remote network management including virus wall appliances.

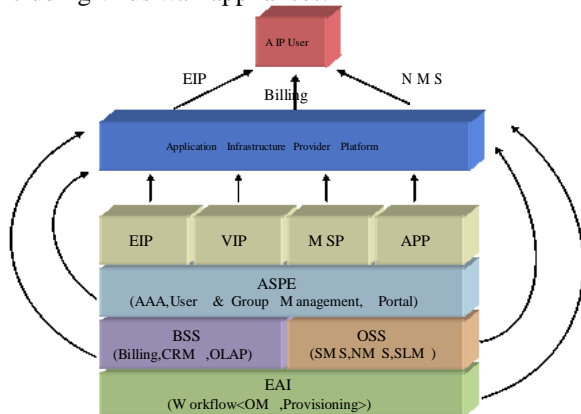

Fig 7. AIP platform usage scenario

AIP is an ASP service platform rent service model that allows independent brand and marketing and admit doing their own ASP business regardless of bizmeka. AIP customers can use the whole platform services or part of them including ASPE (ASP Enabling), BSS (Business Support System), OSS (Operation Support System), EAI (Enterprise Application Integration) subsystem.

### 5. CONCLUSION

For the past 4 years, bizmeka has been evolved from

simple web application hosting provider to today's ASP accepting various demand of customers and developing experimental service model and architecture. But the trend in ASP business is still changing rapidly and bizmeka needs to excavate new service model and its supporting architecture.

KT also strives to solve fundamental problems of ASP business. Like an unreliable service response time due to jittering internet which is inevitable in current best-effort TCP/IP network. But that can be overcome with successful transition to NGN (Next Generation Network) after 2007. Insecure communication problem is solved by KT's VPN (Virtual Private Network) service which can be bundled with any solutions in bizmeka.

But the most hard-to-solve fundamental problem is anxiety and unrest feelings of customers that their valuable data might be drained to public or opponents. But this problem can be solved by reliable cryptography technologies and technological advance over all IT area in near future.

### ACKNOWLEDGEMENT

bizmeka<sup>®</sup> is the official trade mark of KT's ASP business.

### ABSTRACT

An integrated optimization model of production plan and scheduling is introduced. Function objective is to minimize sum of total setup cost (initial setup cost and related setup cost), stock cost, production cost and overtime cost. Restraint functions include equilibrium stock, production capacity, as while as scheduling restraints (procedure restriction and machine capacity restriction). Feasible plan can be set down with considering scheduling restraints.

**Key words:** integrated optimization, production plan, scheduling, schedule restraints

### 1. INSTRUCTION

In machine tool Industry, machine shop can be differentiated into two types: small part with large batch and big part with small batch. The former shop floor produces machine tool axes, cover, tray and special figure part, type of product vary a lot, lot size is large, production cycle is short, plan change frequently, lot size includes monthly batch, semi-monthly batch, weekly batch and daily batch as a result of large lot size delivered and frequently stock. Enterprise plan includes yearly production plan, quarterly production plan and monthly production plan. Manufacturing department in factory deliver monthly product plan to shop floor, and monthly product plan is carried into execution in shop floor. Planner in shop floor set down shorter part production planning, they generally confirm part lot size and turn of delivering parts by experience, thereby result in large work-in-process, infeasible plan and imbalance production. Traditional hierarchical plan decomposed in MRP II often results in infeasible plan in scheduling system as for without considering schedule restraints, new method to establish plan must be adopted.

The kernel goal of plan in batch shop floor is to ascertain part lot size during each period and minimize sum of total setup cost and stock cost. For batch production, literature [1~4] proposed integrated optimization method for production planning and scheduling. Literature [1] put forward integrated model of production planning and scheduling in shop floor, decompose planning alternatively for instances with setup time and without setup time in Job-shop, but the method can only convergence at local optimization results. Literature [2] set up an integrated model of production planning and scheduling in shop floor, schedule restrictions as procedure restraint and machine capacity restraint are taken into account, and its Lagrange relaxation-based solution approach is described, but the method is hard to solve large scale problem for the complexity of the arithmetic to relax

schedule sub-problem. Literature [3] give a heuristic method aiming at complex assembly product manufacturing, optimization lot size is made certain by grouping orders and schedule by searching primary meshwork routes, and function objective is to minimize sum of setup time, stock cycle and total delivery cycle, but lot size in multi-periods is not discussed. In literature [4], an integrated general model of lot-sizing and scheduling is described for multi-stage, multi-resources flexible flow-line, function objective is to minimize sum of total setup cost, stock cost and overtime cost, but production cost and schedule restraints are not considered.

According as merit and demerit of above-mentioned integrated model for production planning and scheduling in batch manufacturing, an integrated optimization model of production planning and scheduling for batch production is recommended, function objective is to minimize sum of total setup time, stock cost, production cost and overtime cost, schedule restrictions include stock equilibrium, procedure restraints, production capacity and machine capacity. The model is non-linear, mixed, integer programming. Genetic arithmetic is an overall optimization searching method with strong adaptability and better extended capacity, its convergence can be amended by linking with heuristic and other searching method, and it can be used to solve complex non-linear problem<sup>[5]</sup>. A mixed, heuristic genetic arithmetic will be used to search results of above-mentioned model in future research.

### 2. INTEGRATED OPTIMIZATION OF PRODUCTION PLANNING AND SCHEDULING FOR BATCH PRODUCTION

In machining workshop of batch production in machine tool industry, type of product varies from several to many, parts processed monthly change constantly with much kinds. Machining workshop has multiplicate equipments, and per equipment has one or more machines. For variable market, shop floor production

planning must be dynamic, real-time and agile. In this paper, an integrated optimization model of production planning and scheduling is described in the context of axes workshop section in shenyang primo machine tool company, which belongs to medium batch production with much kinds. It decomposed workshop sections' monthly part production planning into weekly cell part production planning, and each part's weekly lot size is fixed on.

Axes workshop section belongs to small part with large batch production, includes four production lines: shaft, principal axis, spindle and caudal core, parts are processed separately in each production line, several machine tools are in overtime. Working procedure length, part complexity, cell equipments' capacity, production balance and assemblage of whole product are main factors considered while to set down planning. Scheduling factors include rough material, tools, equipments and staff.

Cell weekly production planning is lot-sizing problem. Lot-sizing planning is to allot batch and process time of process items collection, so as to meet definite capability target. Considering within finite plan span in shop floor,  $N$  kinds of parts are processed on  $M$  machine tools, and each part is processed on machine tool in same order. Setup time of part  $j$  on machine  $k$  is correlated to type of former part  $i$  processed. Plan span is separated into  $T$  period, and exterior requirement  $d_{jt}$  for each part in period  $t$  is known. Objective of lot-sizing planning is to arrange item lot size in each period, and to minimize sum of total setup cost, stock cost and production cost during whole plan period on the condition of meeting restrictions.

Supposing: 1) Lot size must meet exterior requirements during each period; 2) During each period, a part must be processed without interrupted, other part must be machined after the part; 3) Overtime is permitted, but excess cost brought must be considered.

Integrated optimization model of production planning and scheduling meeting above conditions is as follows:

$$J = \min \sum_{j=1}^N \sum_{k=1}^M \sum_{t=1}^T sc_{0jk} Z_{jt} + \sum_{i=1}^N \sum_{j=1}^N \sum_{k=1}^M \sum_{t=1}^T sc_{ijk} Y_{ijt} + \sum_{j=1}^N \sum_{t=1}^T (p_{jt} X_{jt} + h_{jt} I_{jt}) + \sum_{k=1}^M \sum_{t=1}^T oc_k O_{kt} \quad (1)$$

Subject to:

$$I_{j,t-1} + X_{jt} - d_{jt} = I_{jt} \quad \forall j \in N, \forall t \in T \quad (2)$$

$$\sum_{j=1}^N \sum_{k=1}^M p_{jk} X_{jt} + \sum_{j=1}^N \sum_{k=1}^M st_{0jk} Z_{jt} + \sum_{i=1}^N \sum_{j=1}^N \sum_{k=1}^M st_{ijk} Y_{ijt} \leq C_{kt} + Q_{kt}, \forall t \in T \quad (3)$$

$$Y_{ijt} B - X_{jt} \geq 0 \quad \forall i \in \{0, N\}, \forall j \in N, \forall t \in T \quad (4)$$

$$\sum_{j=1}^N Z_{jt} = 1 \quad \forall t \in T \quad (5)$$

$$X_{jt}, I_{jt}, O_{kt} \geq 0 \quad \forall j \in N, \forall t \in T, k \in M \quad (6)$$

$$Y_{ijt} Z_{jt} \in \{0, 1\}, \forall i \in N, \forall j \in N, \forall t \in T \quad (7)$$

Known parameters:  $d_{jt}$ —independent requirements of item  $i$  in period  $t$ ;  $p_{jt}$ —unit production cost of item  $j$  in period  $t$ ;  $p_{jk}$ —machining time of item  $j$  on machine  $k$ ;  $st_{ijk}$ —setup time from item  $i$  to item  $j$  on machine  $k$ , if  $i=0$ , denote initial setup time of item  $j$  on machine  $k$ ;  $sc_{ijk}$ —setup cost from item  $i$  to item  $j$  on machine  $k$ , if  $i=0$ , denote initial setup cost of item  $j$  on machine  $k$ ;  $h_{jt}$ —unit stock cost of item  $j$  during period  $j$  to  $j+1$ ;  $C_{kt}$ —usable throughput of machine  $k$ ;  $oc_k$ —overtime cost of machine  $k$  during unit time;  $B$ —a very large plus.

Decision-making variables:  $I_{jt}$ —stocks of item  $j$  on period  $t$ ;  $O_{kt}$ —overtime of machine  $k$  on period  $t$ ;  $X_{jt}$ —production quantity of item  $j$  on period  $t$ ;  $Z_{jt}$ —setup variables, if  $Z_{jt}=1$ , denote setup course to process item  $j$  at the end of period  $t$  or at the beginning of period  $t+1$ , other instance  $Z_{jt}=0$ ;  $Y_{ijt}$ —setup variables, if  $Y_{ijt}=1$ ,  $i \neq j$ , denote setup course to process item  $j$  after item  $i$  processed, other instance  $Y_{ijt}=0$ .

Objective function (1) is to minimize sum of total setup cost (initial setup cost + related setup cost), stock cost and overtime cost during whole plan period. Restriction (2) is essential stock balance equation. Restriction (3) is inequality of capacity restraints. Restriction (4) denotes setup can only happen while production quantity is plus and border upon items are different. Restriction (5) denotes that each item has only one initial setup. Restriction (6) denotes that decision-making variables are not minus. Restriction (7) means that setup variables are 0 or 1. But above-mentioned model not includes following schedule restrictions:

- Procedure restraints: each item has several working procedure with definite order.
- Capacity restraints: a machine can only process one item on any time.

To describe these schedule restraints, such parameters are defined:  $J_{jt}$ —an item batch task ( $j, t$ ), namely item  $j$  processed on period  $t$ , its production quantity is  $X_{jt}$ ,  $\forall j \in N, \forall t \in T$ ;  $J_t$ — $N$  task collection must be

completed during period  $t$ ,  
 $J_t = \{J_{1t}, J_{2t}, \dots, J_{Nt} \mid \forall t \in T\}$ ;  $J$ —all the task  
 collection,  $J = \bigcup_{t=1}^T J_t$ ;  $s_{jt}$ —setup variables,  

$$s_{jt} = \begin{cases} 1, & X_{jt} > 0 \\ 0, & X_{jt} = 0 \end{cases}; O_{jkt}$$
—operation of job  $J_{jt}$  on  
 machine  $k$ ;  $t_{jkt}$ —time begin to operate  $O_{jkt}$ ;  $OM_k$ —  
 collection of all the operations on machine  $k$ ,  
 $OM_k = \{O_{jmt} \mid m = k, j \in N, t \in T\}$ ;  $OP_j$ —  
 collection of all the operations of item  $j$ ;  
 $OP_j = \{O_{jkt} \mid j = j, k \in M, t \in T\}$ ;  $p_{jkt}^u$ —process  
 time of operation  $O_{jkt}$  of unit item  $j$ ;  $\tau_{jkt}$ —setup  
 time of operation  $O_{jkt}$  of unit item  $j$ ;  $GN$ —collection of  
 all the operations with supposed incept and accomplish  
 operations;  $GA$ —versus collection of working  
 procedure composed of all the operations with orders;  
 $GE_k$ —versus collection of working procedure  
 composed of all the operations on machine  $k$ .

In this way, above schedule restraints can be described as follow:

$$t_{jkt} - t_{j'kt} - \frac{p_{jkt}}{p_{j'kt}} X_{j'kt} - \tau_{jkt} s_{jt} \geq 0, \quad (8)$$

$$\forall (O_{jkt}, O_{j'kt}) \in GA$$

$$t_{jkt} - t_{j'kt} - \frac{p_{jkt}}{p_{j'kt}} X_{j'kt} - \tau_{jkt} s_{jt} \geq 0 \quad (9)$$

$$\forall (O_{jkt}, O_{j'kt}) \in GE_k$$

$$t_{jkt} \geq 0 \quad O_{jkt} \in GN \quad (10)$$

$$s_{jt} \in \{0, 1\}, \forall j \in N, t \in T \quad (11)$$

Restraint (8) denotes turns between working procedures of the same item; restraint (9) denotes turns between items processed on the same machine tool; restraint (10) shows decision-making variables are not minus; restraint (11) expresses that setup variables are 0 or 1.

Integrated optimization model of production planning and scheduling with considering lot-sizing and scheduling restraints as follow:

$$J = \min \sum_{j=1}^N \sum_{k=1}^M \sum_{t=1}^T sc_{ojk} Z_{jt} + \sum_{i=1}^N \sum_{j=1}^N \sum_{k=1}^M \sum_{t=1}^T sc_{ijk} Y_{ijt} \quad (1)$$

$$+ \sum_{j=1}^N \sum_{t=1}^T (p_{jt} X_{jt} + h_{jt} I_{jt}) + \sum_{k=1}^M \sum_{t=1}^T oc_k O_{kt}$$

Subject to: formula (2) ~ (11).

### 3. CONCLUSIONS

Motivated by the aim of improving the feasible plan level of short plan period in a real case, an integrated optimization model of production planning and scheduling has been proposed in weekly item batch confirming.

The function objective is to minimize sum of total setup cost (initial setup cost + related setup cost), stock cost and overtime cost of item within whole planning period. To ascertain lot size, detailed schedule restraints are discussed, so as to get hold of a feasible production planning.

As for schedule restrictions, procedure restraints and capacity restraints are debated. Procedure restraints are described as each item has several working procedure with definite order, and capacity restraints are put forward by way of a machine can only process an item on any time. A mixed, heuristic genetic arithmetic will be used to search the results of above-mentioned model in next research work.

### ABSTRACT

In the business process management, many business process execution languages such as XPD L, BPML, BPEL4WS have been specified with different origins and goals. Most of all, XPD L proposed by WfMC has been widely used in the related applications, especially workflows whose concepts are currently interchangeable with those of business processes. On the other hand, Business Process Modeling Notation (BPMN) driven by BPMI has recently been specified as a standardized graphical notation for a business process. We can therefore commonly design and analyze various business processes using the design tools to support BPMN. Notice that a BPMN-formed business process should be converted to its semantically equivalent business process languages such as XPD L which can consequently be executed by business process engines. In this regard, we propose a transformation mechanism from BPMN-formed business processes to corresponding XPD L processes.

**Keywords:** BPMN, XPD L, business process

### 1. INTRODUCTION

With an increasing number of business applications that automate business processes, many enterprises have recently devoted considerable attention to business process integration. The primary goal of business process integration is inter-operating the information flows between IT organizations that have used a number of various terms to describe how components can be connected together to build complex business processes. For instance, if our system tries to connect a partner during operating a business process, that is composed of tasks such as catalogue request, order, order processing, and dispatching, we must be required business process integration technologies. It is necessarily required many costs for reducing the difference between methodologies of each vendor. For merging business processes, which are located in distributed environment, there is a standard interface that provides flexibility or interoperability between business processes. To streamline business operations, it is important to define a standard business process language in the first place that could be adapted in complex business circumstances. It is a same reason that the computing resource is composed by the programming language such as C or Java. However, a business process language is not relied on a physical object such as operating systems or devices, but it must be designed suitably in a logical meaning of a business environment. Especially, it should be defined a mechanism that one internal partner connects dynamically the other external partners in distributed environments. In order to meet these requirements, researches of the business process language have been broadly going to two trends.

The first of these trends is a research in business process modeling language. It is lately remarkable by Business

Process Modeling Notation (BPMN) Working Group. Although a business analyst doesn't know any information about an internal mechanism of a business process execution, it allows him to design a business process using a business process modeling notation. Examples of other notations or methodologies that were reviewed are UML Activity Diagram, UML EDOC Business Processes, IDEF, ebXML BPSS, Activity-Decision Flow (ADF) Diagram, RosettaNet, LOVeM, and Event-Process Chains (EPCs). BPMN has more functionality and extensibility than other business process modeling languages. So, we select BPMN for mapping from a business process modeling language to a business process execution language.

The second of these trends is a research in business process execution language. It enables a system to understand all of the information which makes our business runs. Representatively, Business Process Modeling Language (BPML) is developed by the Business Process Management Initiative (BPMI), Business Process Execution Language for Web services (BPEL4WS) is written by developers from BEA Systems, IBM, and Microsoft, and XML Process Definition Language is announced by the Workflow Management Coalition (WfMC). And they are XML-based business process execution languages. To minimize a modification of existing workflow applications using XPD L, we select XPD L among a number of business process languages.

Although there is a significant difference between two trends, both in motivating business process modeling and in their features, they have a strong common basis. Thus, the convergence of two major trends is creating a rapidly growing demand for a new breed of software that facilities automation of business processes both between enterprises and within an enterprise. However,

the difference between business processes represents a partial meaning difference, but it raises enormously the risk. In this paper, we describe how the mapping mechanism reduces a meaning difference between BPMN and XPDL. Figure 1 illustrates the mapping structure of this paper; in the future we will plan to study mapping mechanisms from BPMN-formed business processes to BPEL4WS and BPML business processes.

Figure 1. Transformation structure of BPMN

The remainder of the paper is organized as follows. Section 2 presents an overview of related work. Section 3 describes Mapping from BPMN to XPDL. Section 4 contains concluding remarks.

## 2. RELATED WORK

There are several researches in mapping from business process modeling notation to business process execution language [1,3,4,5,6]. This Section describes mapping mechanisms which have already been proposed.

[3] describes the mapping from BPMN to XPDL. It shows that BPMN notations can be transformed to XPDL straightforwardly, because of similar business process structures within them. However, there are BPMN notations which can not be mapped to XPDL, straightforwardly. Therefore mapping is applicable to only 10 BPMN notations. So, we will show the mechanism which can be applicable to other BPMN notations, either, in this paper.

[1] describes the mapping from BPMN to BPEL4WS. It is accomplished by analyzing cases which BPMN business process can be expressed. It also describes all elements and attributes of BPMN mapping to BPEL4WS elements. So, the number of pages of [1] is more than 50. It may be complete, but it is too complex to be proved.

[4] and [5] describe the mapping from UML Diagram to XPDL. [4,5] shows business process can be expressed using UML Diagram, and be mapped to XPDL. [4] describes it using Use Case Diagram, Statechart Diagram, and Activity Diagram with stereotypes, which is defined extendedly, such as <<Route>>, <<No>>, <<Tool>>, <<Subflow>>, <<Loop>>. [5] describes it using only Activity Diagram with stereotypes, which is defined extendedly, such as <<Business Document>>.

[6] describes the mapping from UML Diagram to BPEL4WS. It shows business process can be expressed using Class Diagram and Activity Diagram with

stereotypes, which is defined extendedly, such as <<Process>>, <<Activity>>.

As shown in above, many researches select UML Diagrams as a notation for business process modeling more actively than BPMN. However, if we use UML Diagram to model business process, and if we want to transform the business process to a business process language, we will need to extend the stereotypes which are dependent on transformed languages.

Besides, there are several researches in expression power of business process modeling notations or business process execution languages [7,8,9,10,11,12]. (e.g., workflow patterns, Petri-net)

Like this, mapping mechanisms, which the existing papers propose, are straightforward, case by case analyzed, or system dependent formed. If a mechanism is straightforward, it will be not complete, since a difference of a notation and a language. If a mechanism is case by case analyzed, it will be too complex to be mapped, since it has to be analyzed in all cases. And if a mechanism is language dependent formed, it will be not appropriate for a standard mechanism. Therefore this paper proposes a mapping mechanism from BPMN to XPDL, which is not only simple, complete, but also system interchangeable.

## 3. MAPPING FROM BPMN TO XPDL

Both BPMN and XPDL are conceived of as a directed graph structure. So Mapping from BPMN to XPDL may be described straightforwardly. e.g., A Task and a Sub-Process of BPMN are transformed to an Atomic Activity and a Subflow Activity of XPDL respectively, and a Sequence Flow of BPMN is transformed to a Transition of XPDL [3]. But because BPMN is designed to model and to manage business processes and XPDL is designed to execute business processes, we need to consider some differences between BPMN and XPDL. Firstly BPMN has several elements that are not for executing business processes but only for modeling or managing business processes. These BPMN elements do not need to map to XPDL elements. Secondly, BPMN has several elements that are for executing business processes but do not transformed to XPDL elements straightforwardly. The business processes, which are represented using BPMN including these elements, have to be transformed to the same meaning XPDL business processes.

This Section describes mapping from BPMN to XPDL as follows. In section 3.1 we extract a BPMN element set, which consists of the BPMN elements that have to map to XPDL elements. In section 3.2 we look around the BPMN-formed business processes as a structural point of view and compare these with XPDL business processes. In section 3.3 we describe the mapping from BPMN to XPDL straightforwardly and in section 3.4 we

propose the transformation mechanism for BPMN elements which are not mapped to XPD elements.

3.1 Analysis on BPMN Elements

Business processes are designed by business analysts using BPMN notations, these BPMN-formed business processes are transformed to XPD processes for executing business processes, and the executing business processes are managed by business process managers in BPMN format. That is, the BPMN consists of elements for business process design, elements for business process execution, and elements for business process management, so several BPMN elements, which are not for business process execution, don't need to be transformed to XPD elements.

Figure 2. Major elements defined within BPMN

Figure 2 shows the major elements of BPMN and those categories. In the Business Process Diagram, the graphical objects (Flow Objects, Connecting Objects, Swimlanes, and Artifacts) define Processes (business processes); Flow Objects define the behavior of Processes, Swimlanes group other elements and assign roles to them, Artifacts provide additional information about the Processes, and Connecting Objects represent the order of Flow Objects or association between each element. But Swimlanes, Artifacts, and some of Connecting Objects (Message Flow and Association) are not related to the business process execution. First, a role, which is represented by Swimlanes, is a semantic element which means the role of doing the work (e.g. Seller, Buyer, Client, and etc.). But the element, which we need to know for executing business process, is not a role, but a performer. Second, Artifacts and Association are not directly related to the flow of process. Third, Message Flow shows the flow of messages between two entities, but the actual message is not transmitted by Message Flow but by applications or web services which is bound by Flow Objects. Therefore we don't need to transform these BPMN elements to XPD elements. Moreover, each BPMN elements have their attributes, and some of the attributes (i.e. Name, Author, Language, CreationDate, ModificationDate, GraphicElements, Status, Categories, InputSets, Input, OutputSets, Output, BoundaryVisible) are not related to business process execution. And there is no need to transform these attributes to XPD elements, either. Figure 3 shows the BPMN elements, except the elements which are described above. That is, these elements are related to business process execution and have to be transformed to XPD elements.

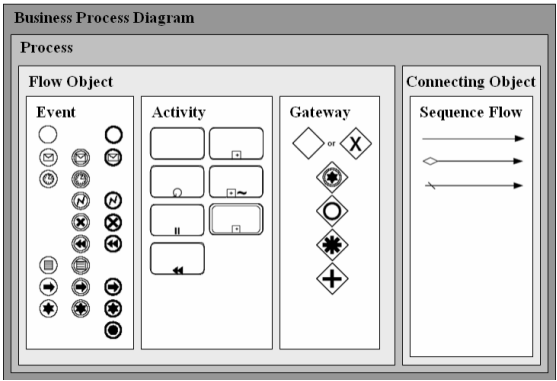

Figure 3. BPMN elements which have to be transformed to XPD elements

3.2 Structural Mapping

A business process is a behavioral flow which is structured by performers, services, and data. In a business process, works, which is performed by performers using services and data, are defined orderly.

Figure 4. Business process structures of BPMN and XPD

BPMN and XPD represent business processes similarly, as shown in Figure 4. Processes, which are defined by BPMN elements, are structured by Flow Objects and Connecting Objects in directed graph format. Also, Workflow Processes, which are defined by XPD, are structured by Activities and Transitions in directed graph format. Like this, Business Process Diagram, Processes, Flow Objects, and Sequence Flows in BPMN are mapped to Package, Workflow Process, Activity, and Transition in XPD respectively.

Table 1. Structural mapping

BPMN element	XPD element
Business Process Diagram	Package
Process	Workflow Process
Flow Object	Activity
Connecting Object	Transition

And performers, services, and data which are the elements of business processes are represented Performer, Implementation, Property in BPMN, and Performer, Tool, Data Field in XPD.

Table 2. Business process elements mapping

BPMN element	XPD element
Performer (within Activity)	Performer (within Activity)
Implementation (within Activity)	Tool (within Activity)
Property (within Process and Activity)	Data Field (within Workflow Process)

### 3.3 Simple Mapping

In Section 3.2, we described that BPMN Flow Objects and Connecting Objects are mapped to XPD L Activities and Transitions. But BPMN Flow Objects and Connecting Objects are classified with Events, Activities, Gateways, and Sequence Flows, and these are classified more detailed according to the value of type related attribute. This Section describes mapping from these detailed BPMN elements to XPD L elements which are transformed straightforwardly.

#### 3.3.1 Events

BPMN Event acts as an event, which occurs, or reacts against another event. (e.g., cancel of an order, modification of an order, and handling these events) And it is classified according to its position (Start, Intermediate, End) and the type of Trigger (Message, Timer, Error, Cancel, Compensation, Rule, Link, Complex, Terminate).

Table 3. BPMN Event mapping to XPD L

BPMN element	XPD L element
None Start Event	Route Activity
None End Event	Route Activity
Message Start Event	Route Activity and Formal Parameters of Workflow Process
Message End Event	Atomic Activity and Route Activity
Acyclic Timer Start Event	Route Activity and No Implementation Atomic Activity including Deadline
Acyclic Timer Intermediate Event (Normal Flow)	No Implementation Atomic Activity including Deadline
Acyclic Timer Intermediate Event (Exception Flow)	Deadline of Atomic Activity

In XPD L, there are some elements which it functions as a BPMN Event. But because XPD L is on the basis of data-based control, many of them are not supported. Therefore, we describe these Events, which is not transformed to XPD L yet, in Section 3.4.

#### 3.3.2 Activities

BPMN Activity is work that is performed within a business process. Activity is classified into Sub-Process and Task according to the subject of the work, and these are classified more detailed according to the method that it works. And we can transform it into XPD L Activity as shown in Table 4 and Table 5.

Table 4. BPMN Sub-Process mapping to XPD L

BPMN element	XPD L element
Embedded Sub-Process	Block Activity
Independent Sub-Process	Subflow Activity
Reference Sub-Process	Block Activity or Subflow Activity equivalent to the Activity referenced

Table 5. BPMN Task mapping to XPD L

BPMN element	XPD L element
Service Task	Atomic Activity
Receive Task	Atomic Activity
Send Task	Atomic Activity
User Task	Atomic Activity including Performer
Script Task	Atomic Activity including Extended Attribute which can contain the script
Manual Task	Manual Mode Atomic Activity
Reference Task	Activity equivalent to the Activity referenced

We didn't describe the Mapping from Ad-Hoc Sub-Process to XPD L yet. But because it is a kind of complex mapping, we describe it in Section 3.4.

#### 3.3.3 Gateways

BPMN Gateway controls the flow of both diverging and converging Sequence Flow. And the types of Gateway are classified according to split/merge and the function. In XPD L, Route Activity implement split or join transitions, and it works as BPMN Gateways according to Transition Restriction element within Route Activity.

Table 6. BPMN Gateway mapping to XPD L

BPMN element	XPD L element
Exclusive Decision (XOR) –Data-Based	XOR Split Route Activity
Exclusive Merge (XOR) –Data-Based	XOR Join Route Activity
Inclusive Decision (OR)	AND Split Route Activity
Inclusive Merge (OR)	AND Join Route Activity
Parallel Fork (AND)	AND Split Route Activity
Parallel Join (AND)	AND Join Route Activity
Complex Decision / Merge	Combination with several Route Activities and Transitions

We didn't describe the mapping from Event-Based Exclusive Decision to XPD L yet. But because it is a kind of complex mapping, we describe it in Section 3.4.

#### 3.3.4 Sequence Flow

BPMN Sequence Flow shows the order of Flow Objects. And the types of Sequence Flow are classified according to the value of Condition attribute. In XPD L, as described in Section 3.3, Transition implements like this. And the type of Transition is classified according to Condition element, either.

Table 7. BPMN Sequence Flow mapping to XPD L

BPMN element	XPD L element
Sequence Flow	Transition
Conditional Sequence Flow	Transition including CONDITION Type Condition
Default Flow	Transition including OTHERWISE Type Condition

### 3.4 Complex Mapping

Complex mapping is the mapping for BPMN elements (complex elements) which XPD L didn't have as the same function. That is, if we recompose a business

process, which is composed of BPMN elements including the complex elements, to a business process, which is composed of BPMN elements except complex elements, we can transform the business process to XPD. It is the same as if “ $A = B$ ” and “ $B = C$ ”, then “ $A = C$ ”. This paper proposes following three mechanisms for these transitive mapping.

### Mechanism 1. Loop

The Loop means that it works more than one time. We can apply this mechanism to the complex element, if the element has the semantic of “it works repeatedly” or “it works again”.

Figure 5. Loop transformation mechanism

### Mechanism 2. Discriminator

The Discriminator means that it completes only a work of all other works which are implemented concurrently. We can apply this mechanism to the complex element, if the element has the semantic of “it finishes B or C”.

Figure 6. Discriminator transformation mechanism

### Mechanism 3. Serialization

The Serialization means that it transforms something, which is serialized implicitly, to another thing serialized explicitly. We can apply this mechanism to the complex element, if the element has the semantic of “it works in the order of a basis”.

Figure 7. Serialization transformation mechanism

Firstly, Cyclic Timer Event, Standard Loop Activity, Sequential MultiInstance Loop Activity, and StartQuantity attribute of Activity apply to the Loop; Cyclic Timer Event represents the work which is implemented in a cycle. Standard Loop and Sequential MultiInstance Loop Activity represents the work which is implemented repeatedly according to the Condition of Activity. StartQuantity attribute of Activity represents the work which waits until the number of token is satisfied. And the Figure 8 shows the application of the Loop transformation mechanism to these BPMN elements.

Secondly, Message Intermediate Event (Exception Flow), Error Event, Multiple Event, Terminate Event, and Event-Based Exclusive Decision apply to the

Discriminator; Both Message Intermediate Event (Exception Flow) and Error Event mean that whether it flows normal flow or exception flow. Multiple Event means that if one of the Event, which is assigned to itself, occurs, it will be triggered. Terminate Event means that it interrupts all the works, which is working in the process, and end the process at once instead of normal end. Event-Based Exclusive Decision means that only one of the Events, which are in order, can be triggered. And the Figure 9 shows the application of the Discriminator transformation mechanism to these BPMN elements.

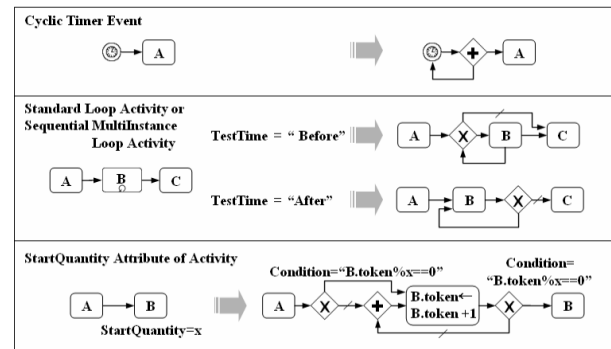

Figure 8. Loop transformation class

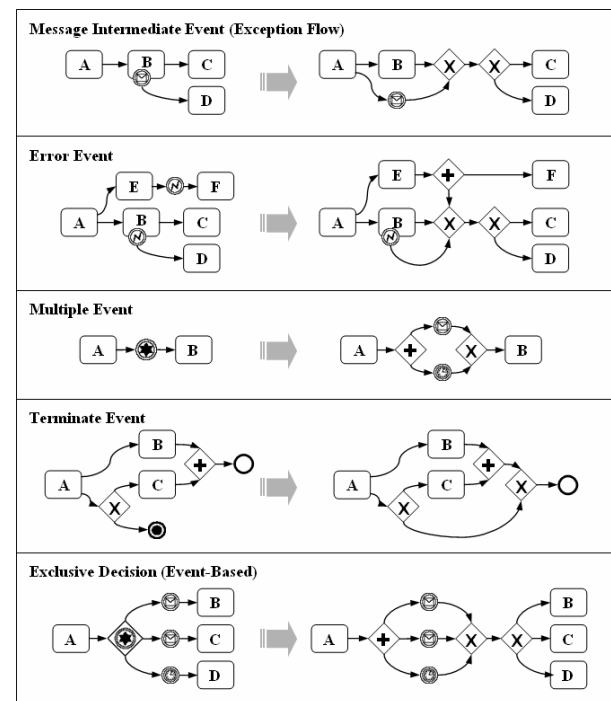

Figure 9. Discriminator transformation class

Thirdly, Link Event and Parallel MultiInstance Loop Activity apply to the Serialization; Link Event represents the work which is to be connected to another Link Event which has same LinkId. Parallel MultiInstance Loop Activity means that it works same work in parallel. And Figure 10 shows the application of the Serialization transformation mechanism to these BPMN elements.

Lastly, Ad-Hoc Sub-Process is the Process which the order of the works and the end of the process is decided by performers at execution time. So it works beginning with the work, which is selected by a performer, repeatedly until the CompletionCondition of the Ad-Hoc Process is satisfied. Therefore Ad-Hoc Process applies to both Loop and Discriminator. Figure 11 shows the application of the transformation mechanisms to Ad-Hoc Sub-Process.

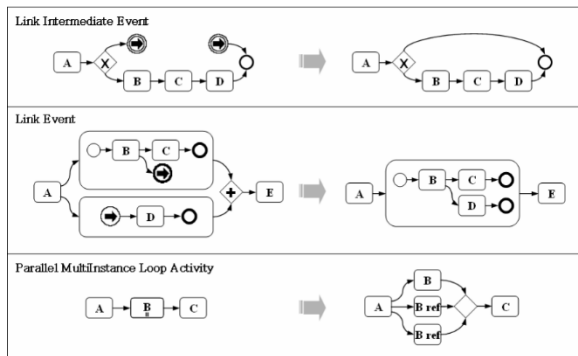

Figure 10. Serialization transformation class

Figure 11. Transformation of Ad-Hoc Sub-Process

#### 4. CONCLUSIONS

This paper focused on a problem which has arisen from a meaning difference between BPMN and XPD L. We have analyzed elements that are mapped from BPMN to XPD L, and then have proposed three transitive mapping mechanisms (loop, discriminator and serialization).

While the existing mapping mechanisms only selected elements that can be directly mapped, we discovered all of elements that are able to be mapped with a notation's transformation without a meaning loss. These methodologies transform a complex BPMN element into several kinds of atomic and simple BPMN elements. That is, because a reconstructed business process is composed of elements, which are adapted to mapping to XPD L, we can transform the BPMN- Formed Business Processes to XPD L Processes.

We are going to develop a module with this mapping mechanism. We will also plan to study mapping mechanisms from BPMN to other business process execution languages such as BPEL4WS and BPML.

### ABSTRACT

As seen in the wide range of researches, the lack of a proper and profitable business model is an important factor in companies' failure and in the use of Internet and e-business. In this paper we want to determine the best (or portfolio of) e-business models for each organization by which they can use Internet and information technologies in the optimal manner in their business. To do so, we will consider strategies, organizational and environmental conditions of each organization and determine the best e-business models in the base of these conditions. So two steps appraisal process be introduced, that can improve the earlier frameworks and remove their disadvantages and also it can assist managers in the choice phase of decision-making.

**Keywords:** electronic business models, decision making process, organizational characteristics

### 1. INTRODUCTION

The Internet is challenging the economic, social, and technological foundations of the old economy. In essence a revolution is taking place, entrepreneurs developing new models for business, the economy, and government. A business model is a method of doing business by which a company can generate revenue to sustain itself. The model spells out how the company adds value, which customers are willing to pay for, in terms of the goods and/or services the company produces in the course of its operations (Turban, 2002, p.8). Many companies are starting to use the Internet to communicate with both, their customers and suppliers, creating new digital electronic commerce networks that bypass traditional distribution channels. The Internet, the web, and intranets can help companies achieve new levels of competitiveness and efficiency, but one of the management challenges that they raise is finding a successful Internet business model (Laubom, K. et al, 2001, pp.251-252).

Nowadays from all sides –from investors, stock market analysts, employees, customers, suppliers and competitors –have pressured to senior managers of 'Old Economy' companies to migrate from marketplace to marketspace (Weil et al, 2001), in other side developing e-business models for conducting e-business is not simply about the adoption of new technologies. It also concerns changes in work practices, in customer/supplier relationships, in the way products are delivered to consumers, in marketing practices and changes in staff skills needed to support e-business. Accordingly, e-business models signify new opportunities for re-organizing the way businesses are currently practiced (Vassilopoulos and et al., 2001). It can be said that the companies' first action in moving toward e-business is the choice of the best e-business model because in e-business models all the changes that are mentioned are regarded and explained. But nobody has introduced a

complete methodology for choosing e-business models up to now. Also the evaluation of all the e-business models is very difficult. So this paper attempt to introduce a methodology for choosing the proper e-business models for organizations by introducing the factors that effect on the portfolio of e-business models.

In proposed methodology shortcomings of prior works is removed and all phases of Simon's decision-making process (intelligence, design, choice) is covered so systematic decision making for choosing e-business models is presented. In order to introduce the mentioned methodology, the result of Hayes and Tjan works are addressed.

The paper is organized as follows. The second section presents the e-business model concept and an overview of current understanding of e-business models in the literature. Section three expresses the Simon's decision-making process. Section four explains e-business models classifications as they are reported in the current literature and Then Tjan's model is introduced. In Section 5, Methodological approach for evaluating e-business models in real world is proposed and finally suggestion and conclusions is expressed.

### 2. E-BUSINESS MODEL CONCEPT

The benefits of living in a fast changing information society would become evident if effective e-business practices are implemented, offering companies exposure and access to global markets and consumer access to customized, high quality services. Innovative and effective e-business models facilitate such practices (Vassilopoulos and et al., 2001).

The term *Business Model* rose to prominence In the 1990s with the advent of IT-centered businesses. The rise of the term is closely related to the emergence and diffusion of commercial activities on the Internet.

Internet start-ups used the term to differentiate themselves from the incumbents and to explain their competitive position. The term appeared first in 1970s in computer science journals, after 1995 also in popular business and computer magazines like *Business Week* or *Wired* before it gained access into peer-reviewed journals focusing on the emerging field of e-commerce and e-business. Today the term is frequently used also in other management journals like *Harvard Business Review* (Stahler, 2001). Accelerating growth of IT and ICT has raised the interest for changing traditional business models or developing new business models that better exploit the opportunities offered by technological innovations. That is why within the last few years, the discussions about business models and the impact of the Internet on them have become more topical (Pateli et al., 2002). However, there is still no common understanding of how a business model is defined, how to develop business models, which are the principal business models, how to transform business models, etc (Alt and Zimmerman, 2001). In other words, there is no consolidated knowledge considering various aspects of business models.

A research made by the Institute of Strategic Change of Accenture (Linder & Cantrell, 2000) concluded that:

“Developing a sound business model matters for making money. However, business models wear out, and firms must alter them in order to remain viable. The better managers know their business model, the more better they can manage patterns of change”. That reveals that understanding business models is a prerequisite for organizations that wish to change their business to remain competitive. A number of cases in which the understanding and use of business model is essential:

1. Understanding the key elements and mechanisms in a specific business domain and their relationships (Osterwalder & Pigneur, 2002).

2. Communicating and sharing the understanding of a business model among business or technology stakeholders (Gordijn & Akkermans, 2001c).

3. Experimenting with innovative business concepts to determine if current business models can be easily adapted to new concepts (Eriksson & Penker, 2000), as well as to assess the viability of new business initiatives (Weill & Vitale, 2001).

4. Specifying valid requirements for the Information Systems that support the business model (Eriksson & Penker, 2000)

5. Identifying options for changing and improving the current business model (Eriksson & Penker, 2000), thus facilitating change (Osterwalder & Pigneur, 2002).

Table 1. Business Model Definitions

Researchers	Definition
Magretta (2002)	A story that explains how an enterprise works.
Petrovic et al. (2001) Auer & Follack (2002)	A description of the logic of a “business system” for creating value that lies behind the actual processes.
Jutla, Bodorik, Wang, (1999)	The business model determines processes and transactions. (i.e. business process- retail [external, internal], procurement, transaction- buy, payment registration etc.)
Applegate (2001)	A description of a complex business that enables study of its structure, the relationships among structural elements, and how it will respond to the real world.
Timmers (1998)	Architecture for the product, service and information flows, including a description of the various business actors and their roles; a description of the potential benefits for the various business actors; and descriptions of sources of revenues.
Osterwalder & Pigneur (2002)	A description of the value a company offers to one or several segments of customers and the architecture of the firm and its network of partners for creating, marketing and delivering this value and relationship capital, in order to generate profitable and sustainable revenues streams.
Weill & Vitale (2001)	A description of the roles and relationships among a firm’s consumers, customers, allies and suppliers that identifies the major flows of product, information, and money, and the major benefits to participants
Tapscott et al. (2000)	A business model is about the invention of new value propositions that transform the rules of competition, and mobilize people and resources to unprecedented levels of performance.

Several attempts have been made so far to define e-business models. Table 1 presents the widely cited definition provided by Timmers (1998) as well as some other definitions suggested more recently in the literature. These definitions range from generic (Magretta, 2002; Petrovic et al., 2001) to more concrete ones (Timmers, 1998; Weill & Vitale, 2001; Osterwalder & Pigneur, 2002). Thus, we can find definitions that explain what the purpose of a business model is, while other definitions focus on specifying its primary elements, and possibly their interrelationships.

Furthermore some researchers perceive the Business Model as a purely business concept that explains the logic of making business for a firm (Timmers, 1998; Linder & Cantrell, 2000; Petrovic, 2001; Rappa, 2001), while some others consider it as a link between strategy, business processes, and information systems (Nilsson et al., 1999; Osterwalder & Pigneur, 2002). The difference between these two interpretations of Business Models concerns the relationship of Business Model with the concepts of Strategy, Business Processes, and Technology. While in the first

interpretation the three concepts are included in the description of Business Model, the second interpretation considers them as inter-linked components set in different levels of a pyramid construct. In this paper, a business model is considered as the conceptual and architectural implementation (blueprint) of a business strategy and represents the foundation for the implementation of business processes and information systems.

### 3. DECISION MAKING PROCESS

Decision-making is regarded as one of the most important activities carried out by an organization (Simon, 1960). Simon has distinguished two extremes regarding the structuredness of decision problems. At one end of the spectrum are well-structured problems that are repetitive and routine and for which standard models have been developed. Simon calls these programmed problems, example of such problem is weekly scheduling of employees. At the other end of the spectrum are unstructured problems, also called nonprogrammed problems, which are novel and non-recurrent such as evaluating an electronic commerce initiative. Semistructured problems fall between the two extremes (Turban et al, 2001,p.43). The decision to engage in electronic business can be seen as non-programmed as new strategies and new technologies are required (Hayes et al., 2003).

Systematic decision-making process according to Simon, involves three major phases: intelligence, design, and choice. Simon's model is the most concise, and yet completes characterization of rational decision-making. In the intelligence phase the reality is examined and the problem is identified and defined. Importance of this phase is that impossible solutions are eliminated which saves in time and money. In the design phase, potential alternative solutions are identified and criteria are set for evaluation of the alternative courses of action. The choice phase includes selection of a proposed solution to the model (not to the problem it represents). (Turban et al., 2001,p41)

Choice is the critical act of decision-making. The choice phase is the one in which actual decision is made and where the commitment to follow a certain course of action is made. The boundary between the design and choice phases is often unclear because certain activities can be performed during both the design and choice phases and because one can return frequently from choice activities to design activities. The choice phase includes search, evaluation, and recommendation of an appropriate solution to the model.

Little research has been conducted on determining appropriate ebusiness models and strategies despite its importance to organizational decision-makers. Finnegan and Golden (1995) propose that the adoption

of electronic business applications is based on two factors; market receptivity and the probability of competitor adoption. Coltman et al. (2001) highlight the importance of the organizational environment to decisions regarding electronic business. Hayes and Finnegan (2003) have attempted to help decision makers with the intelligence phase in relation to assessing the potential of e-business models. Their research identified a set of organizational factors, or organizational prerequisites, that are critical for the successful assessing ebusiness models. Decision makers can use this list of organizational prerequisites to help focus decision-making activity at the intelligence phase.

This paper aims to utilize the prerequisites concept to develop a methodological approach to help managers focus on all phases of decision-making (intelligence, design, choice) by excluding electronic business models that are not compatible with prevailing organizational, environmental/supply chain conditions in first level of evaluation and choosing of appropriate ebusiness model by considering other factors that introduced by Tjan (2001) in second level of evaluation. In fact this proposed approach is extended of Hayes's model.

### 4. E-BUSINESS MODELS CLASSIFICATION

A great deal of research has been directed towards classifying business models and grouping them into specific categories. The business models belonging to the same category usually share some common characteristics, such as the same pricing policy or the same customer relationship model Pateli, Giaglis, 2003. The taxonomy frameworks of Business Models that are presented in the literature differentiate based on two factors: a) *Criteria* posed for classifying Business Models, b) *Objects classified*, whether they are entire business initiatives (such as Amazon, eBay, etc), possibly combining multiple business models (Timmers, 1998; Rappa, 2001), or atomic business models that can be incorporated into an ebusiness initiative (Weill & Vitale, 2001). The most common sets of criteria are:

- *Interaction Pattern and Value Chain Integration* (Timmers, 1998),
- *Functional Integration and Degree of Innovation* (Timmers, 1999),
- *Core Activities and Price –Value Balance* (Linder & Cantrell, 2000),
- *Economic control (both hierarchical and self-organizing) and value integration* (Tapscott et al., 2000),
- *Sourcing: What businesses buy (manufacturing versus operating inputs) against how they buy (systematic versus spot sourcing)* (Kaplan & Sawhney, 2000).

- *Degree of value integration (low to high) and control (self-organizing to hierarchical) in the supply chain (Ticoll et al., 1998)*

The existence of multiple sets of criteria suggests that there are no established and commonly agreed to criteria for classifying business models, but some criteria, such as Value Integration, may be used in various taxonomy frameworks. Moreover, most taxonomy frameworks seem to be narrowly defined for Internet e-Business models. A notable exception is found in Tapscott et al. (2000), who introduce a rather generic taxonomy of Business Models that could apply not only to Internet but also to any type of electronic business featured by a network structure.

In order to construct the proposed model, we have examined classification theories of particular electronic business models based on the work of different researchers specially Hayes et al. (2003) and Tjan (2001). It is clear from such research that particular models are more likely to operate under certain conditions.

Hayes et al. (2003) by combining the work of Ticoll et al. (1998), Timmers (1999), and Kaplan and Sawhney (2000) proposed that electronic business models could be classified according to how they exhibit varying degrees of economic control, value chain integration, functional integration, business innovation and technical innovation. They developed the prerequisites framework for assisting decision makers assess the suitability of electronic business models during the intelligence phase of the decision making process and not in other phases. The basis of their prerequisites model is shown in Table 2. This framework hypothesizes that a particular business model is more likely to succeed in a particular industrial sector when the characteristics of the sector match the conditions required for the model. The framework has the potential to help decision makers by providing a

method of excluding from consideration those electronic business models that are unsuitable for given prevailing organizational and environmental characteristics.

In this paper we extend this framework to consider all phases of Simon's decision-making process (intelligence, design, choice) by utilizing Tjan's model as second level evaluation because in this model financial and human aspects and other factors that influence the viability of particular electronic business models have been identified.

Tjan (2001) adopted a business project portfolio applications approach to create an Internet portfolio-planning matrix. However, instead of trading off industry growth and market position, here the strategy is based on *company fit*, which can be either low or high, and the *project's viability*, which can also be low or high. Together these create an *Internet portfolio map (matrix)*. A business model's viability can be assessed on a scale of 1 to 100, by four criteria: market-value potential, time to positive cash flow, personnel requirements, and funding requirements. Then, an average score (simple average) for each metric is computed. For *fit*, the following criteria are used: alignment with core capabilities, alignment with other company initiatives, fit with organizational structure, fit with company's culture and values, and ease of technical implementation. Then each of business models is assessed on a qualitative scale of high, medium, low. The various e-business models are then mapped on the *Internet portfolio matrix*, based on the average scores for viability and fit. The Internet matrix is divided into four cells, as shown in Figure1. If both *viability* and *fit* are low, the project is killed. If both are high, then the project is adopted. If *fit* is high, but *viability* is low, the project is sent to redesign. Finally, if the *fit* is low but the *viability* is high, the project may be sold or spun off.

Table 2. Characteristics of E-Business Models (Hayes et al., 2003)

Business model	Economic Control	Functional Integration	Supply chain Integration	Innovation	Sourcing
E-shop	Low	Low	Low	Low	Systematic
E-mall	Low	Medium	Low	Medium	Systematic
E-procurement	Medium	Medium	Medium	Medium	Systematic
E-auction	Low	Medium	Medium	Medium	Spot/systematic
Information brokerage	Low	Low	Low	High	Not applicable
Trust services	Low	Low	Low	Medium	Not applicable
Third party marketplace	High	High	High	High	Spot/systematic
E-hubs	High	High	High	High	Spot/systematic
Virtual communities	Medium	Medium	High	High	Not applicable
Value-chain integrators	High	High	High	High	Not applicable
Value-chain service providers	Low	Medium	Medium	High	Not applicable
Collaboration platforms	Low	High	High	High	Not applicable

Figure1. Internet Portfolio Map (Tjan, 2001)

## 5. USING THE PROPOSED METHODOLOGICAL APPROACH

This methodological approach is used to change the current business model toward proper e-business model and it will be useful for the companies that are doing there business traditionally and at the same time want to experience e-business and use of internet in their operations. To do so, in this section a framework is proposed that helps organizational decision makers to select the proper e-business model by a two step appraisal process. In the primary step of this appraisal process, at first those models, which have less chance to be selected, would be identified and ignored for the next step. Doing so results in reduction in cost and time because there will be little number options to be appraised in detail. You can find more detail about this step in the next section. This approach has been improved in comparison with previous models and has removed their disadvantages. Also it has covered all of the Simon's decision-making phases (intelligence, design and choice) and has introduced a systematic procedure to make decision about business model choice. Another specification of this framework is introduction of new criteria that can be useful in e-business model selection.

### 5.1 Primary appraisal: deletion of unsuitable business models

This step of appraisal covers intelligence and design phases of decision-making process. The aim of this step is to exclude those electronic business models that are not suitable given prevailing organizational and environmental characteristics. So in the next step there will be the little number of business models that should be appraised more thoroughly and therefore it results saving in time and cost of choosing proper e-business model. Using Hayes model is proposed method for identification of unsuitable business models, because by using this model it is possible to determine organizational and environmental condition by measuring economic control, value of supply chain integration, value of functional integration, degree of innovation and sourcing. In table 3 we can see the rating scales were completed by senior managers within the food company known to the authors. The calculated scores and associated rating for the company

are shown in Table 3. Low, medium and high rating are determined as being 0–34%, 35–69%, and 70–100% (respectively) of the available marks. The ratings in Table 3 were then compared with the characteristics of e-business models previously shown in Table 2. An extract of the results is shown in Table 4. The ratings in parenthesis are those required for individual e-business models from Table 2. The five models in the table are unsuitable due to the differences between the company scores and the model characteristics. So in this step we ignore them and appraise the remained 7 business models.

### 5.2 Secondary appraisal: selection of suitable business models

In this step the remained models from the previous step that are potentially suitable for the company are appraised more accurately, regarding Tjan model's criteria. For this purpose, at first quantitative criteria of *viability* for each of the e-business models is assessed in the 0 to 100 scale (table 5) and then qualitative criteria of *fit* assessed in the base of intellectual scales (low, medium, high) (table 6). Then, by regarding the average of obtained scores, the position of regarded business models is determined on the Internet Portfolio Matrix (fig 2). As we can see, regarding implemented appraisal, the company should employ portfolio of e-shop, e-procurement and information brokerage models.

## 6. CONCLUSION

Today there are too many pressures on companies to use Internet and Information Technology in their business activities and go forward to e-business. But almost they don't know how to use this new knowledge and technologies. In this paper a methodological approach introduced that can be decision-makers' guideline in selection of suitable business model. In this framework the previous models disadvantages have been removed and also it has covered all of the Simon's decision-making phases (intelligence, design and choice) and has introduced a systematic procedure to make decision about business model choice. Also by performing a two-step appraisal process, it ignores the business models that have less probability to be selected, in the first step and cause to reduction in cost and time for choosing suitable business model. The Proposed approach is conceptual, and has not been empirically tested at this point. Our findings from the pre-test of this model are positive. However, further testing is required.

## ABSTRACT

Business process modeling has been adopted widely. Due to the complexity, it is very hard to validate the rationality of process models. The existing validation methods can only detect structural conflicts in process models. It is also very important to validate those objects related to the processes. This paper presents a rationality validation method which is based on discrete event simulation technology. It can detect three logic mistakes from business process models: structural deadlock, lack of synchronization and objects not matched each other. This method has extended the scope of rationality validation, and also enriches the contents that can be validated.

**Keywords:** Business Process Models, Rationality Validation, Simulation

## 1. INTRODUCTION

Business process model is kind of description of business process. By using model, we are able to analyze the performance of process, to guide the implementation of process, to monitor the execution of process, to enable the management of process. Due to the complexity of business process, whether describing AS-IS models or designing TO-BE models, it is possible to make kinds of mistakes about rationality. It is nonsense to analyze the performance of a process based on the wrong models, and implementing a wrong model may bring huge losing to an enterprise. Therefore, more and more attention has been pay to the validation of business process model.

Validation of a business process model is not so easy. If the structure and size are not limited, it will be an NP hard problem to validating a process model<sup>[1]</sup>. Thus many efforts have been pay to how to improve the efficiency of validation algorithm, hoping to get high efficiency through simplifying model or adding restrict conditions. H. Lin<sup>[2]</sup> gave a graphic reduction method to validate the mistakes of structural deadlock and lack of synchronization of a process based on his process modeling language. W.M.P.<sup>[3]</sup> defined a WF-NET based on Petri-Net, then used Petri-Net theories to validate the rationality of the structure of a process. These methods have gain efficiency of multinomial time complexity. But problems raised here: Firstly, there are rigorous conditions for the algorithms, the method of H. Lin can validate only some specified simple structure of process, method based on Petri-Net required that the process model must be a free-choice net. Secondly, these methods can only find some logic problem of process structure, which is only a little scope of process rationality validation. These methods may have theoretical values, but they are not the practical ones for the real business process.

To support validation of real business process, we have gone on a different way. We haven't cared too much about efficiency of algorithm, but have paid more attention to enlarge the scope of contents of validation, and to improve the practicability. We have developed a validation method based on simulation technology in our eIDEF3 business process model. This method can detect three logic mistakes in business process: structural deadlock, lack of synchronization and objects not matched each other. Compared to the existing methods, it is not so effective, but enough for most business process. And most important, it has extended the scope of rationality validation, and also enriches the contents that can be validated.

## 2. EIDEF3 PROCESS MODELING METHOD

IDEF3 is one of the IDEF series methods. It is used to capture and describe business process. It can support communication and comprehension between domain experts and modelers, and has been used widely in industry. To increase its description ability, support simulation analysis, enlarge model usability, we have extended IDEF3 to eIDEF3 (extended IDEF3), which can describe objects involved in process in a formal way. We have developed a software tool GEM-EASY IDEF3<sup>®</sup> based on this method. Figure 1 is the basic syntactical elements of eIDEF3.

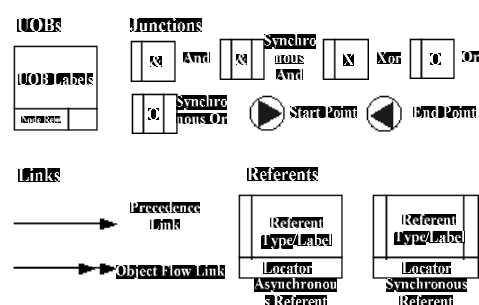

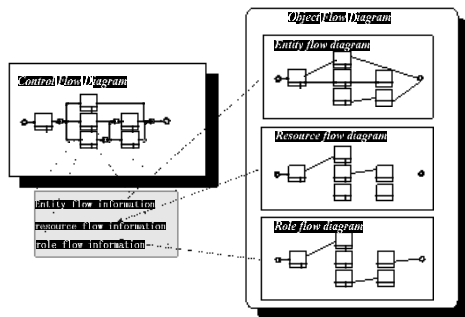

Figure 1 basic syntactical elements of eIDEF3

eIDEF3 provides two type basic flow diagram to describe a process scenario (As shown in Figure 2): One is Control Flow diagram, the other is Object Flow Diagram.

$$\begin{aligned} &\forall n \in N, \\ &\text{if}(n \neq \text{BeginOf}(pis) \wedge n \neq \text{EndOf}(pis)) \\ &\text{then}(n \notin PB \wedge n \notin PE) \end{aligned} \quad (5)$$

It is obviously that this definition of process nationality emphasizes the normally beginning and normally ending of a process. This is consistent with people's intuitive comprehension. More important, this definition is given from process itself, and is not bounded with specified modeling methods. So it is more generic. Moreover, defining process rationality based on PIS has built the foundation to validate it by using simulation method.

#### 4. PROCESS RATIONALITY CRITERION IN EIDEF3 MODEL

Before give the concrete algorithm, we will give the criterion based on some precondition and assumption.

##### 4.1 Basic precondition and assumption

Based on the requirement of eIDEF3 syntactical rules, the following basic precondition must be satisfied.

1) An eIDEF3 model P is an all connected diagram from Start Point to End Point. No isolated nodes exist. That is:

$$\begin{aligned} &\forall n \in P, \\ &\text{InOf}(n) \geq 0 \vee \text{OutOf}(n) \geq 0 \end{aligned} \quad (6)$$

2) Connection rules: The Precedence Links of UOB are single in and single out. The Precedence Links of FanOut Junction are single in and multi out. The Precedence Links of FanIn Junction are multi in and single out. The Precedence Links of Start Point are none in and multi out. The Precedence Links of End Point are multi in and none out. That is:

$$\begin{aligned} &\forall n \in P, \\ &\text{if}(n \in \text{UOB}) \text{then}(\text{InOf}(n) \leq 1 \wedge \text{OutOf}(n) \leq 1) \\ &\text{if}(n \in \text{FanOut\_Junction}) \text{then}(\text{InOf}(n) \leq 1) \\ &\text{if}(n \in \text{FanIn\_Junction}) \text{then}(\text{OutOf}(n) \leq 1) \\ &\text{if}(n = \text{Start\_Point}) \text{then}(\text{InOf}(n) = 0) \\ &\text{if}(n = \text{End\_Point}) \text{then}(\text{OutOf}(n) = 0) \end{aligned} \quad (7)$$

Moreover, we give some basic assumption here, which is only for facilitating description of validation problems, and will not influence the applicability of the algorithm:

1) Synchronous and Asynchronous Junctions are not differentiated. Alternate from synchronous to asynchronous, or from asynchronous to synchronous, will not change the Process Rationality.

2) There is no "Or" junction in process models. Based on the semantic of the "Or" junction, we can use a combination of "And" and "Xor" junction to replace it.

3) There is no feedback in a process. We assume that a process is a DAG (Directed Acyclic Graph). If a feedback is needed, we can put the feedback parts into the decomposed scenario, so that we can avoid dealing with it when using the validation algorithm. Then the rationality of the feedback parts can be determined by other methods.

#### 4.2 Criterion of Process Rationality

We have provided three criterions to validate process rationality, below are the details:

##### 1) Structural Deadlock, SD

If two or more of the FanOut branches of "FanOut Xor" junctions joint in a "FanIn And" junction, SD will happen. That is:

$$\begin{aligned} &\exists n \in \text{FanOut\_Xor\_Junction}, \\ &\text{OutOf}(n) \geq 2 \wedge \\ &\exists n' \in \text{FanIn\_And\_Junction}, \\ &n' \in \text{OutPath}(n)_i \wedge n' \in \text{OutPath}(n)_j, \text{ where } i \neq j \\ &\Leftrightarrow P \text{ is SD} \end{aligned} \quad (8)$$

As shown in figure 4, in this situation, the "FanIn And" junction will not be able to be triggered because it can not finish all of its FanIn branch. Thus the process can not execute any more.

ELSE

{

    Get a rational pis;

}

4. After getting a rational pis, select randomly one of the rest FanOut branch from the tailender "FanOut Xor" junction, repeat step 3, create a new pis;

5. Repeat step 4, until all the "FanOut Xor" junction have been deal with. Then we get all the PISs of the process. Then we can conclude that this process is a rational one;

END

What have to point out is, this algorithm can find the mistake of rationality, and find the node where the mistake exists. But it can not correct the mistake automatically. You have to correct it manually, and execute the algorithm again, because new change may bring new mistakes in other place. Until no mistakes are found, you get a rational process finally.

## 5.2 Analysis of the algorithm

### 1) Completeness

From the step 4 and step 5, we can see that for a rational process, this algorithm can deal with all the fanout branch of the "FanOut Xor" junction. So we can say that this algorithm can explore all PISs of the process. Once there is mistake in the process, the algorithm will come to step 3. Here it can tell where the mistake is. Users can use this message to correct models, and run the algorithm again. Until all mistakes have been corrected, the process will become rational. According to the analysis of last paragraph, all the PISs of a rational process can be explored completely. Therefore, this algorithm is completed. It can explore all PISs of a process, and find all mistakes in it.

### 2) Complexity

It is easy to conclude that for a rational process, to explore all the PISs, the time consumed will increase exponentially along with the amount of "FanOut Xor" junction:

$$O = \bar{c}_{path}^{C_{FanOut\_Xor\_Junction}} \quad (14)$$

Here,  $\bar{c}_{path}$  is the average amount of fanout branch of the "FanOut Xor" junctions.

### 3) Usability

As we have mentioned at the beginning of this paper, most existing validation methods have many limitation in their usability. For example, the method of H. Lin can not validate complex models; the method of W.M.P requires the models must be free-choice. Our method has no rigorous limitation on process models, and the contents that can be validated are more abundant and complete.

Compared to those methods that are based on Petri-net, the complexity of our method is much better. For most

enterprises, a business process will not include too many "FanOut Xor" junctions (where decision making is needed). In the Chinese Aviation CIMS Project, we had build lots of business process models, among these models, the most complex model had no more the 10 "FanOut Xor" junctions. For today's computer, it is very easy to deal with such a complexity.

## 5. CONCLUSION

This paper presents a simulation-based business process rationality validation method. It has extended the scope of rationality validation, and also enriched the contents that can be validated. Although it is not the most efficient one, but for most business processes it is enough. So it is a validation method that is very suited for business process validation. Although this method is created based on eIDEF3, but the concepts about process rationality, process instance sub-graph, are independent of concrete modeling methods. So it is very easy to extend this method to other models, e.g. Petri-net models, workflow models, etc.

## ACKNOWLEDGEMENT

The main result of this paper was created during my doctroal research, which was supported by China 863 Program. The publication of this paper was supported by Scientific Fundation of Ireland.

# Research on Mobile Agent-based E-Commerce System Framework

Wenna Liu<sup>1</sup>, Deli Yang<sup>2</sup>

School of Management, Dalian University of Technology, Dalian 116024, China

<sup>1</sup> wenal@sina.com, <sup>2</sup> somdyang@dlut.edu.cn

## ABSTRACT

Electronic commerce is one of the most important application areas of mobile agent technology. A secure mobile agent system (SMAS) model is established for e-commerce environment. The SMAS consists of mobile agents and mobile agent server. A security shell module in the mobile agent architecture is responsible for mobile agent protection. Surveillance agent running in the agent server provides the host against attacks from malicious agents. Based on the SMAS, mobile agent-based e-commerce system framework is built up and realized in the end.
